New Foreword

On October 1, 2001 Axiom was withdrawn from the market and ended life as a commercial product. On September 3, 2002 Axiom was released under the Modified BSD license, including this document. On August 27, 2003 Axiom was released as free and open source software available for download from the Free Software Foundation's website, Savannah.

Work on Axiom has had the generous support of the Center for Algorithms and Interactive Scientific Computation (CAISS) at City College of New York. Special thanks go to Dr. Gilbert Baumslag for his support of the long term goal.

The online version of this documentation is roughly 1000 pages. In order to make printed versions we've broken it up into three volumes. The first volume is tutorial in nature. The second volume is for programmers. The third volume is reference material. We've also added a fourth volume for developers. All of these changes represent an experiment in print-on-demand delivery of documentation. Time will tell whether the experiment succeeded.

Axiom has been in existence for over thirty years. It is estimated to contain about three hundred man-years of research and has, as of September 3, 2003, 143 people listed in the credits. All of these people have contributed directly or indirectly to making Axiom available. Axiom is being passed to the next generation. I'm looking forward to future milestones.

With that in mind I've introduced the theme of the "30 year horizon". We must invent the tools that support the Computational Mathematician working 30 years from now. How will research be done when every bit of mathematical knowledge is online and instantly available? What happens when we scale Axiom by a factor of 100, giving us 1.1 million domains? How can we integrate theory with code? How will we integrate theorems and proofs of the mathematics with space-time complexity proofs and running code? What visualization tools are needed? How do we support the conceptual structures and semantics of mathematics in effective ways? How do we support results from the sciences? How do we teach the next generation to be effective Computational Mathematicians?

The "30 year horizon" is much nearer than it appears.

Tim Daly
CAISS, City College of New York
November 10, 2003 ((iHy))

Chapter 1

Overview

This book contains the Firefox browser AJAX routines.

1.1 Build Instructions

```
mkdir -p /home/silver/bitmaps
cp bookvol11.pamphlet /home/silver
cd /home/silver
export AXIOM=(where)
export PATH=$AXIOM/bin/lib:$AXIOM/bin:$PATH
notangle -t8 bookvol11.pamphlet > Makefile
make -j 10
axiom -nox
-> )set mes auto off
-> )set out mathml on
-> axServer(8085,multiServ)$AXSERV
```

Now start your browser and go to:

```
file:///home/silver/rootpage.xhtml
```

and then do:

```
Basic Commands -> Calculus -> Differentiate -> Continue
```

```
Basic Commands -> Matrix -> Continue
```

You should see the result of the differentiate appear inline in the page. You can change the values in the text areas, click continue, and see the new result.

1.2 The Makefile

This Makefile assumes that it is being run in the final target directory of the build system. We walk the list of PAGES and untangle them from this file, along with any support files referenced by the pages.

```

(*)≡
BOOK=${SPD}/books/bookvol11.pamphlet
OUT=${MNT}/${SYS}/doc/hypertext

%.xhtml: ${BOOK}
    @ echo making $.xhtml

```

1.3 Building new pages

To add a new page you need to create a page with the default layout below and add the name of the page to the PAGES variable below.

Most of the pages have a default layout of the form:

```
\subsection{pagename.xhtml}
\nwenddocs{}\nwbegincode{3}\moddef{pagename.xhtml}\endmoddef
\LA{}standard head\RA{}
</head>
<body>
\LA{}page head\RA{}
  <div align="center">Page subtitle goes here</div>
  <hr/>
your basic page text goes here.
\LA{}page foot\RA{}
\nwendcode{}\nwbegindocs{4}\nwdocspar
```

There are several things to observe here: `\ol` `\li` Each page lives in its own subsection and its own chunk. `\li` `\li` The pagename and the chunkname are the same `\li` `\li` The chunk includes the `\standard head` `\li` `\li` The chunk includes the `\page head` `\li` `\li` The chunk includes the `\page foot` `\li` `\li` `\ol` The default page layout cannot communicate with Axiom.

1.3.1 Communicating with Axiom

If your page needs to communicate with Axiom you need to add some information in the header of the page. The default page that talks to Axiom has the form:

```
\subsection{pagename.xhtml}
<<pagename.xhtml>>=
<<standard head>>
  <script type="text/javascript">
<<handlefreevars>>
<<axiom talker>>
  </script>
</head>
  <body onload="resetvars();">
<<page head>>
  <div align="center">Page subtitle goes here</div>
  <hr/>
your text goes here
your communication blocks go here
<<page foot>>
```

1.3.2 Handling statements with no free variables

Use a `makeRequest` call with a parameter of the id. Note that the div with id of “ansXX” will get replaced automatically and the “ans” prefix is required.

```
<li>
  <input type="submit" id="p3" class="subbut"
    onclick="makeRequest('p3');"
    value="sin(x)" />
  <div id="ansp3"><div></div></div>
</li>
```

1.3.3 Handling statements with free variables

Free variables exist are used in statements but they are defined in other statements. To make sure the free variables have the correct values you need to include an explicit list of the other ids that need to be executed *before* this statement. You do this with a call to “`handleFree`”. It expects a list, enclosed in brackets, of the ids to execute in order. Be certain that the current id is at the end of the list.

```
<li>
  <input type="submit" id="p10" class="subbut"
    onclick="handleFree(['p9','p10']);"
    value="roman y" />
  <div id="ansp10"><div></div></div>
</li>
```

1.3.4 Handling domain database lookups

Use an anchor tag of the form:

```
<a href="db.xhtml?Vector">Vector</a>
```

This will be interpreted by Axiom to mean that you want to do a lookup on a domain, category, or package whose name follows the question mark. Note that the domain name should NOT be an abbreviation.

1.3.5 Handling `)show domain`

Use a block containing a `showcall` of the form:

```
<li>
  <input type="submit" id="p17" class="subbut"
    onclick="showcall('p17');"
    value=")show DoubleFloat"/>
  <div id="ansp17"><div></div></div>
</li>
```

Note that the “)show” must be at the beginning of the line and that there can only be one space between the word show and the following argument.

1.3.6 Handling lisp expressions

Use a block containing a lispcall of the form: `|li|input type="submit" id="p2" class="subbut" onclick="lispcall('p2');" value="(GETDATABASE '—Matrix— 'CONSTRUCTORMODEMAP)" /li|div id="ansp2" |div|div|div|div|div|div|li|` Note that this works but you can easily blow away your Axiom session with random statements. Let the coder beware.

1.3.7 Handling expressions that have no output

Use the CSS class=“noresult” tag on the input form. This causes the item to show up in black text. It is still executable and is generally executed by handleFree calls because it contains definitions. However, things like function definitions in Axiom return no interesting output so there is no point in clicking on them.

```
<li>
  <input type="submit" id="p5" class="noresult"
    onclick="makeRequest('p5');"
    value=")set streams calculate 5" />
  <div id="ansp5"><div></div></div>
</li>
```

1.4 Defined Pages

Every page in this file is extracted by the Makefile. This is the list of pages that will be extracted. It is organized roughly in the hierarchy that you see in the browser pages. This is convention and is not required.

The page hierarchy (used by the Makefile) is:

```
<PAGES>≡
  PAGES=rootpage.xhtml \
    testpage.xhtml \
    commandline.xhtml \
      menufileopen.xhtml \
      menufileread.xhtml \
      menufilesave.xhtml \
      menufilesaveas.xhtml \
      menufileloadlibrary.xhtml \
      menufileinputfile.xhtml \
      menufiletogglespool.xhtml \
      menufileprint.xhtml \
      menufileexit.xhtml \
```

```

1.5 The Standard Layout

Generally a page has a standard layout using a couple of chunks to minimize the typing. The defined chunks are:

- “standard head” which includes the head element, xmlns, meta, and title element. It also contains the “style” element for CSS information.
- “page head” contains the banner information
- “page foot” contains the trailing page information and the body-end and html-end tags

So the basic layout looks like

```
<<standard head>>
  (local and general javascript goes here)
</head>
<body>
<<page head>>
  (local page definition goes here)
<<page foot>>
```

So all you need to worry about are the actual page forms and the javascript to fetch those forms.

For “active pages”, that is those that communicate with Axiom they generally define a javascript function called “commandline” which formats the request to be sent to the host. You also need to include the “axiom talker” chunk. Note that “axiom talker” expects the “commandline” function to exist and calls it. Thus, for the page that handles differentiation calls to Axiom we add the local javascript:

```
<script type="text/javascript">
  function commandline(arg) {
    return(document.getElementById('comm').value);
  }
<<axiom talker>>
</script>
```

This defined the “commandline” function and embeds the “axiom talker”. The “commandline” function knows how to fetch fields from the rest of the page and format them into a single Axiom string. This is page specific code. For example, this shows a single input line which will be sent to the host when the “Continue” is pressed:

```
<form id="commreq">
  <p>
    Type an input command line to Axiom:<br/>
    <input type="text" id="comm" name="command" size="80"/>
```

```

        <<continue button>>
    </p>
</form>
<<answer field>>

```

Note that the `commandline` function takes an argument which it gets from the caller, `makeRequest`. This argument can be used to distinguish which button was pressed.

The `div` section with `id="mathAns"` is replaced by the result sent from the server.

1.6 Cascading Style Sheet

1.6.1 Standard Style Sheet

This is the standard CSS style section that gets included with every page. We do this here but it could be a separate style sheet. It hardly matters either way as the style sheet is trivial.

```

<style>≡
<style>

html {
    background-color: #ECEA81;
}

body {
    margin: 0px;
    padding: 0px;
}

div.command {
    color:red;
}

div.center {
    color:blue;
}

div.reset {
    visibility:hidden;
}

div.mathml {
    color:blue;
}

```

```
}

input.subbut {
    background-color:#ECEA81;
    border: 0;
    color:green;
    font-family: "Courier New", Courier, monospace;
}

input.noresult {
    background-color:#ECEA81;
    border: 0;
    color:black;
    font-family: "Courier New", Courier, monospace;
}

span.cmd {
    color:green;
    font-family: "Courier New", Courier, monospace;
}

pre {
    font-family: "Courier New", Courier, monospace;
}
</style>
```

1.6.2 Menu style sheet

$\langle menu\ style \rangle \equiv$
`<style>`

```
form {
  margin-top: 0;
  margin-bottom: 0;
  padding-left: 10px;
}

table.main {
  background-color: #ECEA81;
  font-size: 10pt;
  font-family: arial;
}

.main A:link {
  font-family: arial;
  color:#016bbd;
}

.main A:hover {
  font-family: arial;
  color: #64747A;
}

.main A:visited {
  font-family: arial;
  color:#336699;
}

/* style the outer div to give it width */
.menu {
  font-size:0.85em;
}

/* remove all the bullets, borders and padding
   from the default list styling */
.menu ul {
  padding:0;
  width:1000px;
  margin:0;
  list-style-type:none;
  white-space: normal;
}
```

```
.menu ul ul {
    width:90px;
}

/* float the list to make it horizontal and a relative position
   so that you can control the dropdown menu position */
.menu li {
    float:left;
    width:90px;
    position:relative;
}

/* style the links for the top level */
.menu a, .menu a:visited {
    display:block;
    font-size:12px;
    text-decoration:none;
    font-weight:bold;
    color:#2952a7;
    width:99px;
    height:32px;
    line-height:29px;
    border:0px solid #fff;
    border-width:0px 0px 0 0px;
    text-align:center;
}

/* style the second level links
   if this breaks all the level 2 links appear at once */
.menu ul ul a, .menu ul ul a:visited {
    font-size:10px;
    font-weight:normal;
    background:#d4d8bd;
    color:#000;
    height:auto;
    line-height:1em;
    padding:5px 10px;
    width:78px
}

/* style the top level hover */
.menu a:hover, .menu ul ul a:hover{
    border:1px solid #000;
    border-width:1px 1px 0 1px;
}
```

```
.menu :hover > a, .menu ul ul :hover > a {
    border:1px solid #000;
    border-width:1px 1px 0 1px;
}

/* style the second level background */
.menu ul ul a.drop, .menu ul ul a.drop:visited {
    background:#e0d8d0;
}

/* style the second level hover */
.menu ul ul a.drop:hover{
    background:#c9ba65;
}

.menu ul ul :hover > a.drop {
    background:#c9ba65;
}

/* style the third level background */
.menu ul ul ul a, .menu ul ul ul a:visited {
    background:#e2dfa8;
}

/* style the third level hover */
.menu ul ul ul a:hover {
    background:#b2ab9b;
}

.menu ul ul ul :hover > a {
    background:#b2ab9b;
}

/* hide the sub levels and give them a position absolute
   so that they take up no room */
.menu ul ul {
    visibility:hidden;
    position:absolute;
    height:0;
    top:31px;
    left:0;
    width:150px;
}

/* position the third level flyout menu */
```

```
.menu ul ul ul{
    left:100px;
    top:0;
    width:90px;
}

/* position the third level flyout menu for a left flyout */
.menu ul ul ul.left {
    left:-90px;
}

/* style the table so that it takes no part in the layout -
   required for IE to work */
.menu table {
    position:absolute;
    top:0;
    left:0;
}

/* make the second level visible when hover on
   first level list OR link */
.menu ul li:hover ul,
    .menu ul a:hover ul {
    visibility:visible;
}

/* keep the third level hidden when you hover on
   first level list OR link */
.menu ul :hover ul ul {
    visibility:hidden;
}

/* keep the fourth level hidden when you hover on
   second level list OR link */
.menu ul :hover ul :hover ul ul {
    visibility:hidden;
}

/* make the third level visible when you hover over second level list
   OR link */
.menu ul :hover ul :hover ul {
    visibility:visible;
}

/* make the fourth level visible when you hover over third level list
   OR link */
```

```

        .menu ul :hover ul :hover ul :hover ul {
            visibility:visible;
        }

</style>

```

1.7 standard head

This is the standard head section. It is used on pages that do not include javascript. Note that it does NOT include the `;/head;` so the javascript can be added easily.

```

<standard head>≡
  <?xml version="1.0" encoding="UTF-8"?>
  <html xmlns="http://www.w3.org/1999/xhtml"
        xmlns:xlink="http://www.w3.org/1999/xlink"
        xmlns:m="http://www.w3.org/1998/Math/MathML">
    <head>
      <meta http-equiv="Content-Type" content="text/html" charset="us-ascii"/>
      <title>Axiom Documentation</title>
    </head>
  </html>

```

This is the standard page header.

```

<page head>≡
  <div align="center"></div>
  <hr/>

```

This is the standard page foot.

```

<page foot>≡
  </body>
</html>

```

This is the standard continue button

```

<continue button>≡
  <center>
    <input type="button" value="Continue" name="continue"
      onclick="javascript:makeRequest('');"/>
  </center>

```

This is where to place the math answer

```

<answer field>≡
  <div id="mathAns"><div></div></div>

```

1.8 Javascript functions

1.8.1 Show only mathml

This function will show only the mathml result in the response. It is useful for particular pages that have lists of equations where all you care about are the answers.

(showonlymathml)≡

```
<![CDATA[
// The structure returned from Axiom now is
// <div class="stepnum"></div>
// <div class="command"></div>
// <div class="algebra"></div>
// <div class="mathml"></div>
// <div class="type"></div>
// This function will pick up the mathml and put it into 'indiv'
function showanswer(mathString,indiv) {
    var mystr = mathString.split("</div>");
    var mymathstr = mystr[3].concat("</div>");

<div align="center">Group Theory</div>

<hr/>

A group is a set G together with an associative operation $*$ satisfying the axioms of existence of a unit element and an inverse of every element of the group. The Axiom category [Group](db.xhtml?Group) represents this setting. Many data structures in Axiom are groups and therefore there is a large variety of examples as fields and polynomials, although the main interest there is not a group structure.

*
*

*
*

To work with and in groups in a concrete manner some way of representing groups has to be chosen. A group can be given as a list of generators and as a set of relations. If there are no relations, then we have a free group, realized in the domain [FreeMonoid](db.xhtml?FreeMonoid) which won't be discussed here. We consider permutation groups, where a group is realized as a subgroup of the symmetric group of a set, i.e., the group of all bijections of a set, the operation being the composition of maps. Indeed, every group can be realized this way, although this may not be practical.

*
*

*
*

Furthermore group elements can be given as invertible matrices. The group operation is reflected by matrix multiplication. More precise in representation theory group homomorphisms from a group to general linear groups are constructed. Some algorithms are implemented in Axiom.

<page foot>

1.9.6 alggrouptheoryrepa6.xhtml

```

<alggrouptheoryrepa6.xhtml>≡
  <standard head>
    <script type="text/javascript">
      <handlefreevars>
      <axiom talker>
    </script>
  </head>
  <body>
    <page head>
      <div align="center">Representations of A6</div>
      <hr/>

```

In what follows you'll see how to use Axiom to get all the irreducible representations of the alternating group A6 over the field with two elements (GF 2). First, we generate A6 by a three-cycle: $x=(1,2,3)$ and a 5-cycle: $y=(2,3,4,5,6)$. Next we have Axiom calculate the permutation representation over the integers and over GF 2:

```

<ul>
  <li>
    <input type="submit" id="p1" class="subbut"
      onclick="makeRequest('p1');"
      value="genA6:LIST PERM INT:=[cycle [1,2,3],cycle [2,3,4,5,6]]" />
    <div id="ansp1"><div></div></div>
  </li>
  <li>
    <input type="submit" id="p2" class="subbut"
      onclick="handleFree(['p1','p2']);"
      value="pRA6:=permutationRepresentation(genA6,6)" />
    <div id="ansp2"><div></div></div>
  </li>
</ul>

```

Now we apply Parker's 'Meat-Axe' and split it:

```

<ul>
  <li>
    <input type="submit" id="p3" class="subbut"
      onclick="handleFree(['p1','p2','p3']);"
      value="sp0:=meatAxe(pRA6:.(LIST MATRIX PF 2))" />
    <div id="ansp3"><div></div></div>
  </li>
</ul>

```

We have found the trivial module as a quotient module and a 5-dimensional sub-module. Try to split again:

```

<ul>
  <li>
    <input type="submit" id="p4" class="subbut"

```

```

        onclick="handleFree(['p1','p2','p3','p4']);"
        value="sp1:=meatAxe sp0.1" />
    <div id="ansp4"><div></div></div>
</li>
</ul>

```

and we find a 4-dimensional sub-module and the trivial one again. Now we can test if this representation is absolutely irreducible.

```

<ul>
<li>
    <input type="submit" id="p5" class="subbut"
        onclick="handleFree(['p1','p2','p3','p4','p5']);"
        value="isAbsolutelyIrreducible? sp1.2" />
    <div id="ansp5"><div></div></div>
</li>
</ul>

```

and we see that this 4-dimensional representation is absolutely irreducible. So, we have found a second irreducible representation. Now, we construct a representation by reducing an irreducible one of the symmetric group S_6 over the integers mod 2. We take the one labelled by the partition $[2,2,1,1]$ and restrict it to A_6 :

```

<ul>
<li>
    <input type="submit" id="p6" class="subbut"
        onclick="handleFree(['p1','p6']);"
        value="d2211:=irreducibleRepresentation([2,2,1,1],genA6)" />
    <div id="ansp6"><div></div></div>
</li>
<li>
    <input type="submit" id="p7" class="subbut"
        onclick="handleFree(['p1','p6','p7']);"
        value="d2211m2:=d2211::(LIST MATRIX PF 2); sp2:=meatAxe d2211m2" />
    <div id="ansp7"><div></div></div>
</li>
</ul>

```

This gave both a five and a four dimensional representation. Now we take the 4-dimensional one and we shall see that it is absolutely irreducible:

```

<ul>
<li>
    <input type="submit" id="p8" class="subbut"
        onclick="handleFree(['p1','p6','p7','p8']);"
        value="isAbsolutelyIrreducible? sp2.1" />
    <div id="ansp8"><div></div></div>
</li>
</ul>

```

The two 4-dimensional representations are not equivalent:

```

<ul>

```

```

<li>
  <input type="submit" id="p9" class="subbut"
    onclick="handleFree(['p1','p6','p7','p9']);"
    value="areEquivalent?(sp1.2,sp2.1)" />
  <div id="ansp9"><div></div></div>
</li>
</ul>

```

So we have found a third irreducible representation. Now we construct a new representation using the tensor product and try to split it:

```

<ul>
<li>
  <input type="submit" id="p10" class="subbut"
    onclick="handleFree(['p1','p6','p7','p10']);"
    value="dA6d16:=tensorProduct(sp1.2,sp2.1); meatAxe dA6d16" />
  <div id="ansp10"><div></div></div>
</li>
</ul>

```

The representation is irreducible, but it may be not absolutely irreducible.

```

<ul>
<li>
  <input type="submit" id="p11" class="subbut"
    onclick="handleFree(['p1','p6','p7','p10','p11']);"
    value="isAbsolutelyIrreducible? dA6d16" />
  <div id="ansp11"><div></div></div>
</li>
</ul>

```

So let's try the same procedure over the field with 4 elements:

```

<ul>
<li>
  <input type="submit" id="p12" class="subbut"
    onclick="handleFree(['p1','p6','p7','p10','p12']);"
    value="sp3:=meatAxe(dA6d16:(LIST MATRIX FF(2,2)))" />
  <div id="ansp12"><div></div></div>
</li>
</ul>

```

Now we find two 8-dimensional representations, dA6d8a and dA6d8b. Both are absolutely irreducible.

```

<ul>
<li>
  <input type="submit" id="p13" class="subbut"
    onclick="handleFree(['p1','p6','p7','p10','p12','p13']);"
    value="isAbsolutelyIrreducible? sp3.1" />
  <div id="ansp13"><div></div></div>
</li>
<li>
  <input type="submit" id="p14" class="subbut"

```

```

        onclick="handleFree(['p1','p6','p7','p10','p12','p14']);"
        value="isAbsolutelyIrreducible? sp3.2" />
    <div id="ansp14"><div></div></div>
</li>
</ul>

```

and they are not equivalent.

```

<ul>
<li>
    <input type="submit" id="p15" class="subbut"
        onclick="handleFree(['p1','p6','p7','p10','p12','p15']);"
        value="areEquivalent?(sp3.1,sp3.2)" />
    <div id="ansp15"><div></div></div>
</li>
</ul>

```

So we have found five absolutely irreducible representations of A_6 in characteristic 2. General theory now tells us that there are no more irreducible ones. Here, for future reference are all the absolutely irreducible 2-module representations of A_6 .

```

<ul>
<li>
    <input type="submit" id="p16" class="subbut"
        onclick="handleFree(['p1','p2','p3','p16']);"
        value="sp0.2" />
    <div id="ansp16"><div></div></div>
</li>
<li>
    <input type="submit" id="p17" class="subbut"
        onclick="handleFree(['p1','p2','p3','p4','p17']);"
        value="sp1.2" />
    <div id="ansp17"><div></div></div>
</li>
<li>
    <input type="submit" id="p18" class="subbut"
        onclick="handleFree(['p1','p6','p7','p18']);"
        value="sp2.1" />
    <div id="ansp18"><div></div></div>
</li>
<li>
    <input type="submit" id="p19" class="subbut"
        onclick="handleFree(['p1','p6','p7','p10','p12','p19']);"
        value="sp3.1" />
    <div id="ansp19"><div></div></div>
</li>
<li>
    <input type="submit" id="p20" class="subbut"
        onclick="handleFree(['p1','p6','p7','p10','p12','p20']);"

```

```

        value="sp3.2" />
      <div id="ansp20"><div></div></div>
    </li>
  </ul>
  And here again is the irreducible, but not absolutely irreducible
  representations of A6 over GF 2.
  <ul>
    <li>
      <input type="submit" id="p21" class="subbut"
        onclick="handleFree(['p1','p6','p7','p10','p21']);"
        value="dA6d16" />
      <div id="ansp21"><div></div></div>
    </li>
  </ul>
  <page foot>

```

1.9.7 alggrouptheoryrepththeory.xhtml

<alggrouptheoryrepththeory.xhtml>≡

<standard head>

</head>

<body>

<page head>

Representation theory for finite groups studies finite groups by embedding them in a general linear group over a field or an integral domain. Hence, we are representing each element of the group by an invertible matrix. Two matrix representations of a given group are equivalent, if, by changing the basis of the underlying space, you can go from one to the other. When you change bases, you transform the matrices that are the images of elements by conjugating them by an invertible matrix.

*
*

*
*

If we can find a subspace which is fixed under the image of the group, then there exists a 'base change' after which all the representing matrices are in upper triangular block form. The block matrices on the main diagonal give a new representation of the group of lower degree. Such a representation is said to be 'reducible'.

    <page head>
      <div align="center">Computation of Galois Groups</div>
      <hr/>

```

As a sample use of Axiom's algebraic number facilities, we compute the Galois group of the polynomial $p(x)=x^5-5x+12$

```

<ul>
  <li>
    <input type="submit" id="p1" class="subbut"
      onclick="makeRequest('p1');"
      value="p:=x**5-5*x+12" />
    <div id="ansp1"><div></div></div>
  </li>
</ul>

```

We would like to construct a polynomial $f(x)$ such that the splitting field of $p(x)$ is generated by one root of $f(x)$. First we construct a polynomial $r=r(x)$ such that one root of $r(x)$ generates the field generated by two roots of the polynomial $p(x)$. As it will turn out, the field generated by two roots of $p(x)$ is, in fact, the splitting field of $p(x)$.

From the proof of the primitive element theorem we know that if a and b are algebraic numbers, then the field $Q(a,b)$ is equal to $Q(a+k*b)$ for an appropriately chosen integer k . In our case, we construct the minimal polynomial of $a[i]-a[j]$, where $a[i]$ and $a[j]$ are two roots of $p(x)$. We construct this polynomial using [resultant](dbopresultant.xhtml). The main result we need is that if $f(x)$ is a polynomial with roots $a[1] \dots a[m]$ and $g(x)$ is a polynomial with roots $b[1] \dots b[n]$, then the polynomial $h(x)=\text{resultant}(f(y),g(x-y),y)$ is a polynomial of degree $m*n$ with roots $a[i]+b[j]$, $1 \leq i \leq m, 1 \leq j \leq n$.

For $f(x)$ we use the polynomial $p(x)$. For $g(x)$ we use the polynomial $-p(-x)$. Thus, the polynomial we first construct is $\text{resultant}(p(y),-p(y-x),y)$.

```

<ul>
  <li>
    <input type="submit" id="p2" class="subbut"
      onclick="handleFree(['p1','p2']);"
      value="q:=resultant(eval(p,x,y),-eval(p,x,y-x),y)" />

```

```

    <div id="ansp2"><div></div></div>
  </li>
</ul>

```

The roots of $q(x)$ are $a[i]-a[j]$, $1 \leq i, j \leq 5$. Of course, there are five pairs (i, j) with $i=j$, so 0 is a 5-fold root of $q(x)$. Let's get rid of this factor.

```

<ul>
  <li>
    <input type="submit" id="p3" class="subbut"
      onclick="handleFree(['p1','p2','p3']);"
      value="q1:=exquo(q,x^5)" />
    <div id="ansp3"><div></div></div>
  </li>
</ul>

```

Factor the polynomial q_1 .

```

<ul>
  <li>
    <input type="submit" id="p4" class="subbut"
      onclick="handleFree(['p1','p2','p3','p4']);"
      value="factoredQ:=factor q1" />
    <div id="ansp4"><div></div></div>
  </li>
</ul>

```

We see that q_1 has two irreducible factors, each of degree 10. (The fact that the polynomial q_1 has two factors of degree 10 is enough to show that the Galois group of $p(x)$ is the dihedral group of order 10. (ref: McKay, Soicher, Computing Galois Groups over the Rationals, Journal of Number Theory 20, 273-281 (1983). We do not assume the results of this paper and we continue with the computation.) Note that the type of `factoredQ` is

```
<a href="db.xhtml?Factored(Polynomial(Integer))">
```

```
Factored Polynomial Integer</a>.
```

This is a special data type for

recording factorizations of polynomials with integer coefficients (see

```
<a href="factored.xhtml">Factored</a>). We can access the individual
factors using the operation <a href="dbopnthfactor.xhtml">nthFactor</a>.
```

```

<ul>
  <li>
    <input type="submit" id="p5" class="subbut"
      onclick="handleFree(['p1','p2','p3','p4','p5']);"
      value="r:=nthFactor(factoredQ,1)" />
    <div id="ansp5"><div></div></div>
  </li>
</ul>

```

Consider the polynomial $r=r(x)$. This is the minimal polynomial of the difference of two roots of $p(x)$. Thus, the splitting field of $p(x)$

contains a subfield of degree 10. We show that this subfield is the splitting field of $p(x)$ by showing that $p(x)$ factors completely over this field. First we create a symbolic root of the polynomial $r(x)$. (We replaced x by b in the polynomial r so that our symbolic root would be printed as b .)

```
<ul>
  <li>
    <input type="submit" id="p6" class="subbut"
      onclick="handleFree(['p1','p2','p3','p4','p5','p6']);"
      value="beta:AN:=rootOf(eval(r,x,b))" />
    <div id="ansp6"><div></div></div>
  </li>
</ul>
```

We next tell Axiom to view $p(x)$ as a univariate polynomial in x with algebraic number coefficients. This is accomplished with this type declaration:

```
<ul>
  <li>
    <input type="submit" id="p7" class="subbut"
      onclick="handleFree(['p1','p2','p3','p4','p5','p6','p7']);"
      value="p:=p::UP(x,INT)::UP(x,AN)" />
    <div id="ansp7"><div></div></div>
  </li>
</ul>
```

Factor $p(x)$ over the field $Q(\text{beta})$. (This computation will take some time).

```
<ul>
  <li>
    <input type="submit" id="p8" class="subbut"
      onclick="handleFree(['p1','p2','p3','p4','p5','p6','p7','p8']);"
      value="algFactors:=factor(p,[beta])" />
    <div id="ansp8"><div></div></div>
  </li>
</ul>
```

When factoring over number fields, it is important to specify the field over which the polynomial is to be factored, as polynomials have different factorizations over different fields. When you use the operation [factor](dbopfactor.xhtml), the field over which the polynomial is factored is the field generated by

-
 the algebraic numbers that appear in the coefficients of the polynomial

 the algebraic numbers that appear in a list passed as an optional second argument of the operation

In our case, the coefficients of p are all rational numbers and only beta

appears in the list, so the field is simply $\mathbb{Q}(\beta)$. It was necessary to give the list [beta] as a second argument of the operations because otherwise the polynomial would have to be factored over the field generated by its coefficients, namely the rational numbers.

```
<ul>
  <li>
    <input type="submit" id="p9" class="subbut"
      onclick="handleFree(['p1','p9']);"
      value="factor(p)" />
    <div id="ansp9"><div></div></div>
  </li>
</ul>
```

We have shown that the splitting field of $p(x)$ has degree 10. Since the symmetric group of degree 5 has only one transitive subgroup of order 10, we know that the Galois group of $p(x)$ must be this group, the dihedral group of order 10. Rather than stop here, we explicitly compute the action of the Galois group on the roots of $p(x)$.

First we assign the roots of $p(x)$ as the values of five variables. We can obtain an individual root by negating the constant coefficient of one of the factors of $p(x)$.

```
<ul>
  <li>
    <input type="submit" id="p10" class="subbut"
      onclick="handleFree(['p1','p2','p3','p4','p5','p6','p7','p8','p10']);"
      value="factor1:=nthFactor(algFactors,1)" />
    <div id="ansp10"><div></div></div>
  </li>
</ul>
<ul>
  <li>
    <input type="submit" id="p11" class="subbut"
      onclick="handleFree(['p1','p2','p3','p4','p5','p6','p7','p8','p10','p11']);"
      value="root1:=-coefficient(factor1,0)" />
    <div id="ansp11"><div></div></div>
  </li>
</ul>
```

We can obtain a list of all of the roots in this way.

```
<ul>
  <li>
    <input type="submit" id="p12" class="subbut"
      onclick="handleFree(['p1','p2','p3','p4','p5','p6','p7','p8','p12']);"
      value="roots:=[-coefficient(nthFactor(algFactors,i),0) for i in 1..5]" />
    <div id="ansp12"><div></div></div>
  </li>
</ul>
```

The expression `-coefficient(nthFactor(algFactors,i),0)` is the i th root of $p(x)$ and the elements of `roots` are the i th roots of $p(x)$ as i ranges from 1 to 5. Assign the roots as the values of the variables `a1..a5`.

```
<ul>
  <li>
    <input type="submit" id="p13" class="subbut"
      onclick="handleFree(['p1','p2','p3','p4','p5','p6','p7','p8','p12','p13']);"
      value="(a1,a2,a3,a4,a5):=(roots.1,roots.2,roots.3,roots.4,roots.5)" />
    <div id="ansp13"><div></div></div>
  </li>
</ul>
```

Next we express the roots of $r(x)$ as polynomials in β . We could obtain these roots by calling the operation

[factor](dbopfactor.xhtml). `factor(r,[beta])` factors $r(x)$ over $Q(\beta)$. However, this is a lengthy computation and we can obtain the roots of $r(x)$ as differences of the roots `a1,...,a5` of $p(x)$. Only ten of these differences are roots of $r(x)$ and the other ten are roots of the other irreducible factor of q_1 . We can determine if a given value is a root of $r(x)$ by evaluating $r(x)$ at that particular value. (Of course, the order in which factors are returned by the operation

[factor](dbopfactor.xhtml) is unimportant and may change with different implementations of the operation. Therefore, we cannot predict in advance which differences are roots of $r(x)$ and which are not.) Let's look at four examples (two are roots of $r(x)$ and two are not).

```
<ul>
  <li>
    <input type="submit" id="p14" class="subbut"
      onclick=
        "handleFree(['p1','p2','p3','p4','p5','p6','p7','p8','p12','p13','p14']);"
        value="eval(r,x,a1-a2)" />
    <div id="ansp14"><div></div></div>
  </li>
  <li>
    <input type="submit" id="p15" class="subbut"
      onclick=
        "handleFree(['p1','p2','p3','p4','p5','p6','p7','p8','p12','p13','p15']);"
        value="eval(r,x,a1-a3)" />
    <div id="ansp15"><div></div></div>
  </li>
  <li>
    <input type="submit" id="p16" class="subbut"
      onclick=
        "handleFree(['p1','p2','p3','p4','p5','p6','p7','p8','p12','p13','p16']);"
        value="eval(r,x,a1-a4)" />
    <div id="ansp16"><div></div></div>
  </li>
```

```

<li>
  <input type="submit" id="p17" class="subbut"
    onclick=
      "handleFree(['p1','p2','p3','p4','p5','p6','p7','p8','p12','p13','p17']);"
      value="eval(r,x,a1-a5)" />
  <div id="ansp17"><div></div></div>
</li>
</ul>

```

Take one of the differences that was a root of $r(x)$ and assign it to the variable bb . For example, if `eval(r,x,a1-a4)` returned 0, you would enter this.

```

<ul>
<li>
  <input type="submit" id="p18" class="subbut"
    onclick=
      "handleFree(['p1','p2','p3','p4','p5','p6','p7','p8','p12','p13','p18']);"
      value="bb:=a1-a4" />
  <div id="ansp18"><div></div></div>
</li>
</ul>

```

Of course, if the difference is equal to the root β , you should choose another root of $r(x)$.

Automorphisms of the splitting field are given by mapping a generator of the field, namely β , to other roots of its minimal polynomial. Let's see what happens when β is mapped to bb . We compute the images of the roots a_1, \dots, a_5 under this automorphism.

```

<ul>
<li>
  <input type="submit" id="p19" class="subbut"
    onclick=
      "handleFree(['p1','p2','p3','p4','p5','p6','p7','p8','p12','p13','p19']);"
      value="aa1:=subst(a1,beta=bb)" />
  <div id="ansp19"><div></div></div>
</li>
<li>
  <input type="submit" id="p20" class="subbut"
    onclick=
      "handleFree(['p1','p2','p3','p4','p5','p6','p7','p8','p12','p13','p20']);"
      value="aa2:=subst(a2,beta=bb)" />
  <div id="ansp20"><div></div></div>
</li>
<li>
  <input type="submit" id="p21" class="subbut"
    onclick=
      "handleFree(['p1','p2','p3','p4','p5','p6','p7','p8','p12','p13','p21']);"
      value="aa3:=subst(a3,beta=bb)" />

```

```

    <div id="ansp21"><div></div></div>
  </li>
  <li>
    <input type="submit" id="p22" class="subbut"
      onclick=
        "handleFree(['p1','p2','p3','p4','p5','p6','p7','p8','p12','p13','p22']);"
        value="aa4:=subst(a4,beta=bb)" />
    <div id="ansp22"><div></div></div>
  </li>
  <li>
    <input type="submit" id="p23" class="subbut"
      onclick=
        "handleFree(['p1','p2','p3','p4','p5','p6','p7','p8','p12','p13','p23']);"
        value="aa5:=subst(a5,beta=bb)" />
    <div id="ansp23"><div></div></div>
  </li>
</ul>
Of course, the values aa1,...,aa5 are simply a permutation of the values
a1,...,a5. Let's find the value of aa1 (execute as many of the following
five commands as necessary).
<ul>
  <li>
    <input type="submit" id="p24" class="subbut"
      onclick=
        "handleFree(['p1','p2','p3','p4','p5','p6','p7','p8','p12','p13','p19','p24']);"
        value="(aa1=a1)::Boolean" />
    <div id="ansp24"><div></div></div>
  </li>
  <li>
    <input type="submit" id="p25" class="subbut"
      onclick=
        "handleFree(['p1','p2','p3','p4','p5','p6','p7','p8','p12','p13','p20','p25']);"
        value="(aa2=a2)::Boolean" />
    <div id="ansp25"><div></div></div>
  </li>
  <li>
    <input type="submit" id="p26" class="subbut"
      onclick=
        "handleFree(['p1','p2','p3','p4','p5','p6','p7','p8','p12','p13','p21','p26']);"
        value="(aa3=a3)::Boolean" />
    <div id="ansp26"><div></div></div>
  </li>
  <li>
    <input type="submit" id="p27" class="subbut"
      onclick=
        "handleFree(['p1','p2','p3','p4','p5','p6','p7','p8','p12','p13','p22','p27']);"

```

```

        value="(aa4=a4)::Boolean" />
      <div id="ansp27"><div></div></div>
    </li>
    <li>
      <input type="submit" id="p28" class="subbut"
        onclick=
"handleFree(['p1','p2','p3','p4','p5','p6','p7','p8','p12','p13','p23','p28']);"
        value="(aa5=a5)::Boolean" />
      <div id="ansp28"><div></div></div>
    </li>
  </ul>

```

Proceeding in this fashion, you can find the values of aa2..aa5.

You have represented the automorphism $\beta \rightarrow b$ as a permutation of the roots a_1, \dots, a_5 . If you wish, you can repeat this computation for all the roots of $r(x)$ and represent the Galois group of $p(x)$ as a subgroup of the symmetric group on five letters.

Here are two other problems that you may attack in a similar fashion:

```

<ol>
  <li> Show that the Galois group of  $p(x)=x^4+2x^3-2x^2-2x+1$  is the
    dihedral group of order eight. (The splitting field of this polynomial
    is the Hilbert class field of the quadratic field  $\mathbb{Q}(\sqrt{145})$ .)
  </li>
  <li> Show that the Galois group of  $p(x)=x^6+108$  has order 6 and is
    isomorphic to the symmetric group on three letters. (The splitting
    field of this polynomial is the splitting field of  $x^3-2$ .)
  </li>
</ol>
<page foot>

    <page head>
      <div align="center">Derivatives</div>
      <hr/>

```

Use the Axiom function `D` to differentiate an expression.

To find the derivative of an expression f with respect to a variable x , enter $D(f,x)$.

```

<ul>
  <li>
    <input type="submit" id="p1" class="subbut"
      onclick="makeRequest('p1');"
      value="f:=exp exp x" />
    <div id="ansp1"><div></div></div>
  </li>
  <li>
    <input type="submit" id="p2" class="subbut"
      onclick="handleFree(['p1','p2']);"
      value="D(f,x)" />
    <div id="ansp2"><div></div></div>
  </li>
</ul>

```

An optional third argument n in `D` asks Axiom for the n th derivative of f . This finds the fourth derivative of f with respect to x .

```

<ul>
  <li>
    <input type="submit" id="p3" class="subbut"
      onclick="handleFree(['p1','p3']);"
      value="D(f,x,4)" />
    <div id="ansp3"><div></div></div>
  </li>
</ul>

```

You can also compute partial derivatives by specifying the order of differentiation.

```

<ul>

```

```

<li>
  <input type="submit" id="p4" class="subbut"
    onclick="makeRequest('p4');"
    value="g:=sin(x^2+y)" />
  <div id="ansp4"><div></div></div>
</li>
<li>
  <input type="submit" id="p5" class="subbut"
    onclick="handleFree(['p4','p5']);"
    value="D(g,y)" />
  <div id="ansp5"><div></div></div>
</li>
<li>
  <input type="submit" id="p6" class="subbut"
    onclick="handleFree(['p4','p6']);"
    value="D(g,[y,y,x,x])" />
  <div id="ansp6"><div></div></div>
</li>
</ul>

```

Axiom can manipulate the derivatives (partial or iterated) of expressions involving formal operators. All the dependencies must be explicit. This returns 0 since F (so far) does not explicitly depend on x.

```

<ul>
  <li>
    <input type="submit" id="p7" class="subbut"
      onclick="makeRequest('p7');"
      value="D(F,x)" />
    <div id="ansp7"><div></div></div>
  </li>
</ul>

```

Suppose that we have F a function of x, y, and z, where x and y are themselves functions of z. Start by declaring that F, x, and y are operators.

```

<ul>
  <li>
    <input type="submit" id="p8" class="subbut"
      onclick="makeRequest('p8');"
      value="F:=operator 'F; x:=operator 'x; y:=operator 'y" />
    <div id="ansp8"><div></div></div>
  </li>
</ul>

```

You can use F, x, and y in expressions.

```

<ul>
  <li>
    <input type="submit" id="p9" class="subbut"
      onclick="handleFree(['p8','p9']);"

```

```

        value="a:=F(x z, y z, z^2)+x y(z+1)" />
      <div id="ansp9"><div></div></div>
    </li>
  </ul>

```

Differentiate formally with respect to z . The formal derivatives appearing in `dadz` are not just formal symbols, but do represent derivatives of x , y , and F .

```

  <ul>
    <li>
      <input type="submit" id="p10" class="subbut"
        onclick="handleFree(['p8','p9','p10']);"
        value="dadz:=D(a,z)" />
      <div id="ansp10"><div></div></div>
    </li>
  </ul>

```

You can evaluate the above for particular functional values of F , x , and y . If $x(z)$ is $\exp(z)$ and $y(z)$ is $\log(z+1)$, then this evaluates `dadz`.

```

  <ul>
    <li>
      <input type="submit" id="p11" class="subbut"
        onclick="handleFree(['p8','p9','p10','p11']);"
        value="eval(eval(dadz,'x,z+>exp z'),'y,z+>log(z+1))" />
      <div id="ansp11"><div></div></div>
    </li>
  </ul>

```

You obtain the same result by first evaluating a and then differentiating.

```

  <ul>
    <li>
      <input type="submit" id="p12" class="subbut"
        onclick="handleFree(['p8','p9','p10','p12']);"
        value="m:=eval(eval(a,'x,z+>exp z'),'y,z+>log(z+1))" />
      <div id="ansp12"><div></div></div>
    </li>
  </ul>

```

```

  <ul>
    <li>
      <input type="submit" id="p13" class="subbut"
        onclick="handleFree(['p8','p9','p10','p12','p13']);"
        value="D(m,z)" />
      <div id="ansp13"><div></div></div>
    </li>
  </ul>

```

<page foot>

1.9.17 calintegrals.xhtml

```

<calintegrals.xhtml>≡
  <standard head>
    <script type="text/javascript">
      <handlefreevars>
      <axiom talker>
    </script>
  </head>
  <body onload="resetvars();">
    <page head>
      <div align="center">Integration</div>
      <hr/>

```

Axiom has extensive library facilities for integration.

The first example is the integration of a fraction with a denominator that factors into a quadratic and a quartic irreducible polynomial. The usual partial fraction approach used by most other computer algebra systems either fails or introduces expensive unneeded algebraic numbers.

We use a factorization-free algorithm.

```

<ul>
  <li>
    <input type="submit" id="p1" class="subbut"
      onclick="makeRequest('p1');"
      value="integrate((x^2+2*x+1)/((x+1)^6+1),x)" />
    <div id="ansp1"><div></div></div>
  </li>
</ul>

```

When real parameters are present, the form of the integral can depend on the signs of some expressions.

Rather than query the user or make sign assumptions, Axiom returns all possible answers.

```

<ul>
  <li>
    <input type="submit" id="p2" class="subbut"
      onclick="makeRequest('p2');"
      value="integrate(1/(x^2+a),x)" />
    <div id="ansp2"><div></div></div>
  </li>
</ul>

```

The [integrate](dbopintegrate.xhtml) operation generally assumes that all parameters are real. The only exception is when the integrand has complex valued quantities.

If the parameter is complex instead of real, then the notion of sign is undefined and there is a unique answer. You can request this answer by "prepending" the word "complex" to the command name.

```
<ul>
  <li>
    <input type="submit" id="p3" class="subbut"
      onclick="makeRequest('p3');"
      value="complexIntegrate(1/(x^2+a),x)" />
    <div id="ansp3"><div></div></div>
  </li>
</ul>
```

The following two examples illustrate the limitations of table-based approaches. The two integrands are very similar, but the answer to one of them requires the addition of two new algebraic numbers.

This is the easy one. The next one looks very similar but the answer is much more complicated.

```
<ul>
  <li>
    <input type="submit" id="p4" class="subbut"
      onclick="makeRequest('p4');"
      value="integrate(x^3/(a+b*x)^(1/3),x)" />
    <div id="ansp4"><div></div></div>
  </li>
</ul>
```

Only an algorithmic approach is guaranteed to find what new constants must be added in order to find a solution.

```
<ul>
  <li>
    <input type="submit" id="p5" class="subbut"
      onclick="makeRequest('p5');"
      value="integrate(1/(x^3*(a+b*x)^(1/3)),x)" />
    <div id="ansp5"><div></div></div>
  </li>
</ul>
```

Some computer algebra systems use heuristics or table-driven approaches to integration. When these systems cannot determine the answer to an integration problem, they reply "I don't know". Axiom uses an algorithm for integration that conclusively proves that an integral cannot be expressed in terms of elementary functions.

When Axiom returns an integral sign, it has proved that no answer exists as an elementary function.

```
<ul>
  <li>
    <input type="submit" id="p6" class="subbut"
```

```

        onclick="makeRequest('p6');"
        value="integrate(log(1+sqrt(a*x+b))/x,x)" />
    <div id="ansp6"><div></div></div>
</li>
</ul>

```

Axiom can handle complicated mixed functions much beyond what you can find in tables. Whenever possible, Axiom tries to express the answer using the functions present in the integrand.

```

<ul>
<li>
    <input type="submit" id="p7" class="subbut"
        onclick="makeRequest('p7');"
        value="integrate((sinh(1+sqrt(x+b))+2*sqrt(x+b))/(sqrt(x+b)*(x+cosh(1+sqrt(x+b))))),x)" />
    <div id="ansp7"><div></div></div>
</li>
</ul>

```

A strong structure-checking algorithm in Axiom finds hidden algebraic relationships between functions.

```

<ul>
<li>
    <input type="submit" id="p8" class="subbut"
        onclick="makeRequest('p8');"
        value="integrate(tan(atan(x)/3),x)" />
    <div id="ansp8"><div></div></div>
</li>
</ul>

```

The discovery of this algebraic relationship is necessary for correct integration of this function. Here are the details:

```

<ol>
<li>
    If  $x = \tan(t)$  and  $g = \tan(t/3)$  then the following algebraic relationship is true:

```

```

<pre>
    g^3 - 3xg^2 - 3g + x = 0
</pre>

```

```

</li>
<li>
    Integrate g using this algebraic relation; this produces:

```

```

<pre>
((24g^2-8)log(3g^2-1) + (81x^2+24)g^2 + 72xg - 27x^2 - 16) / (54g^2 - 18)
</pre>

```

```

</li>
<li>
    Rationalize the denominator, producing:

```

```

<pre>
    (8log(3g^2-1) - 3g^2 + 18xg + 16)/18
</pre>

```

Replace g by the initial definition $g=\tan(\arctan(x)/3)$ to produce the final result.

This is an example of a mixed function where the algebraic layer is over the transcendental one.

```
<input type="submit" id="p9" class="subbut"
  onclick="makeRequest('p9');"
  value="integrate((x+1)/(x*(x+log x)^(3/2)),x)" />
<div id="ansp9"><div></div></div>
```

While incomplete for non-elementary functions, Axiom can handle some of them.

```
<input type="submit" id="p10" class="subbut"
  onclick="makeRequest('p10');"
  value="integrate(exp(-x^2)*erf(x)/(erf(x)^3-erf(x)^2-erf(x)+1),x)" />
<div id="ansp10"><div></div></div>
```

More examples of Axiom's integration capabilities are discussed in

Integration.

1.9.18 callaplace.xhtml

```

<callaplace.xhtml>≡
  <standard head>
    <script type="text/javascript">
      <handlefreevars>
      <axiom talker>
    </script>
  </head>
  <body onload="resetvars();" >
    <page head>
      <div align="center">Laplace Transforms</div>
      <hr/>

```

Axiom can compute some forward Laplace transforms, mostly of elementary functions not involving logarithms, although some cases of special functions are handled. To compute the forward Laplace transform of $F(t)$ with respect to t and express the result as $f(s)$, issue the command `laplace(F(t),t,s)`.

```

<ul>
  <li>
    <input type="submit" id="p1" class="subbut"
      onclick="makeRequest('p1');"
      value="laplace(sin(a*t)*cosh(a*t)-cos(a*t)*sinh(a*t),t,s)" />
    <div id="ansp1"><div></div></div>
  </li>
</ul>

```

Here are some other non-trivial examples.

```

<ul>
  <li>
    <input type="submit" id="p2" class="subbut"
      onclick="makeRequest('p2');"
      value="laplace((exp(a*t)-exp(b*t))/t,t,s)" />
    <div id="ansp2"><div></div></div>
  </li>
  <li>
    <input type="submit" id="p3" class="subbut"
      onclick="makeRequest('p3');"
      value="laplace(2/t*(1-cos(a*t)),t,s)" />
    <div id="ansp3"><div></div></div>
  </li>
  <li>
    <input type="submit" id="p4" class="subbut"
      onclick="makeRequest('p4');"
      value="laplace(exp(-a*t)*sin(b*t)/b^2,t,s)" />
    <div id="ansp4"><div></div></div>
  </li>
</ul>

```

```

<input type="submit" id="p5" class="subbut"
  onclick="makeRequest('p5');"
  value="laplace((cos(a*t)-cos(b*t))/t,t,s)" />
<div id="ansp5"><div></div></div>
</li>
</ul>

```

Axiom also knows about a few special functions.

```

<ul>
<li>
  <input type="submit" id="p6" class="subbut"
    onclick="makeRequest('p6');"
    value="laplace(exp(a*t+b)*Ei(c*t),t,s)" />
  <div id="ansp6"><div></div></div>
</li>
<li>
  <input type="submit" id="p7" class="subbut"
    onclick="makeRequest('p7');"
    value="laplace(a*Ci(b*t)+c*Si(d*t),t,s)" />
  <div id="ansp7"><div></div></div>
</li>
</ul>

```

When Axiom does not know about a particular transform, it keeps it as a formal transform in the answer.

```

<ul>
<li>
  <input type="submit" id="p8" class="subbut"
    onclick="makeRequest('p8');"
    value="laplace(sin(a*t)-a*t*cos(a*t)+exp(t^2),t,s)" />
  <div id="ansp8"><div></div></div>
</li>
</ul>
<page foot>

```

1.9.19 callimits.xhtml

```

<callimits.xhtml>≡
  <standard head>
    <script type="text/javascript">
      <handlefreevars>
      <axiom talker>
    </script>
  </head>
  <body onload="resetvars();">
    <page head>
      <div align="center">Limits</div>
      <hr/>

```

To compute a limit, you must specify a functional expression, a variable, and a limiting value for that variable. If you do not specify a direction, Axiom attempts to compute a two-sided limit.

Issue this to compute the limit of $(x^2-2x+2)/(x^2-1)$ as x approaches 1.

```

<ul>
  <li>
    <input type="submit" id="p1" class="subbut"
      onclick="makeRequest('p1');"
      value="limit((x^2-3*x+2)/(x^2-1),x=1)" />
    <div id="ansp1"><div></div></div>
  </li>
</ul>

```

Sometimes the limit when approached from the left is different from the limit from the right and, in this case, you may wish to ask for a one-sided limit. Also, if you have a function that is only defined on one side of a particular value, you can compute a one-sided limit.

The function $\log(x)$ is only defined to the right of zero, that is, for $x > 0$. Thus, when computing limits of functions involving $\log(x)$, you probably want a "right-hand" limit.

```

<ul>
  <li>
    <input type="submit" id="p2" class="subbut"
      onclick="makeRequest('p2');"
      value='limit(x*log(x),x=0,"right")' />
    <div id="ansp2"><div></div></div>
  </li>
</ul>

```

When you do not specify "right" or "left" as the optional fourth argument, <dboplmit.xhtml> tries to compute a two-sided limit. Here the limit from the left does not exist, as Axiom indicates when you try to take a two-sided limit.

```

<ul>
<li>
  <input type="submit" id="p3" class="subbut"
    onclick="makeRequest('p3');"
    value="limit(x*log(x),x=0)" />
  <div id="ansp3"><div></div></div>
</li>
</ul>

```

A function can be defined on both sides of a particular value, but tend to different limits as its variable approaches that value from the left and from the right. We can construct an example of this as follows: Since $\sqrt{y^2}$ is simply the absolute value of y , the function $\sqrt{y^2}/y$ is simply the sign (+1 or -1) of the nonzero real number y . Therefore, $\sqrt{y^2}/y = -1$ for $y \leq 0$ and $\sqrt{y^2}/y = +1$ for $y > 0$. This is what happens when we take the limit at $y=0$. The answer returned by Axiom gives both a "left-handed" and a "right-handed" limit.

```

<ul>
<li>
  <input type="submit" id="p4" class="subbut"
    onclick="makeRequest('p4');"
    value="limit(sqrt(y^2)/y,y=0)" />
  <div id="ansp4"><div></div></div>
</li>
</ul>

```

Here is another example, this time using a more complicated function.

```

<ul>
<li>
  <input type="submit" id="p5" class="subbut"
    onclick="makeRequest('p5');"
    value="limit(sqrt(1-cos(t))/t,t=0)" />
  <div id="ansp5"><div></div></div>
</li>
</ul>

```

You can compute limits at infinity by passing either "plus infinity" or "minus infinity" as the third argument of `limit`. To do this, use the constants `%plusInfinity` and `%minusInfinity`.

```

<ul>
<li>
  <input type="submit" id="p6" class="subbut"
    onclick="makeRequest('p6');"
    value="limit(sqrt(3*x^2+1)/(5*x),x=%plusInfinity)" />
  <div id="ansp6"><div></div></div>
</li>
<li>
  <input type="submit" id="p7" class="subbut"
    onclick="makeRequest('p7');"

```

```

        value="limit(sqrt(3*x^2+1)/(5*x),x=%minusInfinity)" />
        <div id="ansp7"><div></div></div>
    </li>
</ul>

```

You can take limits of functions with parameters. As you can see, the limit is expressed in terms of the parameters.

```

<ul>
<li>
    <input type="submit" id="p8" class="subbut"
        onclick="makeRequest('p8');"
        value="limit(sinh(a*x)/tan(b*x),x=0)" />
    <div id="ansp8"><div></div></div>
</li>
</ul>

```

When you use [limit](dboplimit.xhtml), you are taking the limit of a real function of a real variable. When you compute this, Axiom returns 0 because, as a function of a real variable, $\sin(1/z)$ is always between -1 and 1, so $z \cdot \sin(1/z)$ tends to 0 as z tends to 0.

```

<ul>
<li>
    <input type="submit" id="p9" class="subbut"
        onclick="makeRequest('p9');"
        value="limit(z*sin(1/z),z=0)" />
    <div id="ansp9"><div></div></div>
</li>
</ul>

```

However, as a function of a complex variable, $\sin(1/z)$ is badly behaved near 0 (one says that $\sin(1/z)$ has an essential singularity at $z=0$). When viewed as a function of a complex variable, $z \cdot \sin(1/z)$ does not approach any limit as z tends to 0 in the complex plane. Axiom indicates this when we call [complexLimit](dbopcomplexlimit.xhtml).

```

<ul>
<li>
    <input type="submit" id="p10" class="subbut"
        onclick="makeRequest('p10');"
        value="complexLimit(z*sin(1/z),z=0)" />
    <div id="ansp10"><div></div></div>
</li>
</ul>

```

You can also take complex limits at infinity, that is, limits of a function of z as z approaches infinity on the Riemann sphere. Use the symbol `%infinity` to denote "complex infinity". As above, to compute complex limits rather than real limits, use [complexLimit](dbopcomplexlimit.xhtml).

```

<ul>
<li>
    <input type="submit" id="p11" class="subbut"

```

```

        onclick="makeRequest('p11');"
        value="complexLimit((2+z)/(1-z),z=%infinity)" />
    <div id="ansp11"><div></div></div>
</li>
</ul>

```

In many cases, a limit of a real function of a real variable exists when the corresponding complex limit does not. This limit exists.

```

<ul>
<li>
    <input type="submit" id="p12" class="subbut"
        onclick="makeRequest('p12');"
        value="limit(sin(x)/x,x=%plusInfinity)" />
    <div id="ansp12"><div></div></div>
</li>
</ul>

```

But this limit does not.

```

<ul>
<li>
    <input type="submit" id="p13" class="subbut"
        onclick="makeRequest('p13');"
        value="complexLimit(sin(x)/x,x=%infinity)" />
    <div id="ansp13"><div></div></div>
</li>
</ul>

```

<page foot>

1.9.20 calmoreintegrals.xhtml

```

<calmoreintegrals.xhtml>≡
  <standard head>
    <script type="text/javascript">
      <handlefreevars>
      <axiom talker>
    </script>
  </head>
  <body onload="resetvars();">
    <page head>
      <div align="center">Integration</div>
      <hr/>

```

Integration is the reverse process of differentiation, that is, an integral of a function f with respect to a variable x is any function g such that $D(g,x)$ is equal to f . The package

[FunctionSpaceIntegration](db.xhtml?FunctionSpaceIntegration)

provides the top-level integration operation

[integrate](dbopintegrate.xhtml), for integrating real-valued elementary functions.

```

<ul>
  <li>
    <input type="submit" id="p1" class="subbut"
      onclick="makeRequest('p1');"
      value="integrate(cosh(a*x)*sinh(a*x),x)" />
    <div id="ansp1"><div></div></div>
  </li>
</ul>

```

Unfortunately, antiderivatives of most functions cannot be expressed in terms of elementary functions.

```

<ul>
  <li>
    <input type="submit" id="p2" class="subbut"
      onclick="makeRequest('p2');"
      value="integrate(log(1+sqrt(a*x+b)),x)" />
    <div id="ansp2"><div></div></div>
  </li>
</ul>

```

Given an elementary function to integrate, Axiom returns a formal integral as above only when it can prove that the integral is not elementary and not when it cannot determine the integral. In this rare case it prints a message that it cannot determine if an elementary integral exists. Similar functions may have antiderivatives that look quite different because the form of the antiderivative depends on the sign of a constant that appears in the function.

```

<ul>

```

```

<li>
  <input type="submit" id="p3" class="subbut"
    onclick="makeRequest('p3');"
    value="integrate(1/(x^2-2),x)" />
  <div id="ansp3"><div></div></div>
</li>
<li>
  <input type="submit" id="p4" class="subbut"
    onclick="makeRequest('p4');"
    value="integrate(1/(x^2+2),x)" />
  <div id="ansp4"><div></div></div>
</li>
</ul>

```

If the integrand contains parameters, then there may be several possible antiderivatives, depending on the signs of expressions of the parameters. In this case Axiom returns a list of answers that cover all possible cases. Here you use the answer involving the square root of a when $a > 0$ and the answer involving the square root of $-a$ when $a \leq 0$.

```

<ul>
  <li>
    <input type="submit" id="p5" class="subbut"
      onclick="makeRequest('p5');"
      value="integrate(x^2/(x^4-a^2),x)" />
    <div id="ansp5"><div></div></div>
  </li>
</ul>

```

If the parameters and the variables of integration can be complex numbers rather than real, then the notion of sign is not defined. In this case all the possible answers can be expressed as one complex function. To get that function, rather than a list of real functions, use [complexIntegrate](dbopcomplexintegrate.xhtml), which is provided by the package [FunctionSpaceComplexIntegration](db.xhtml?FunctionSpaceComplexIntegration).

This operation is used for integrating complex-valued elementary functions.

```

<ul>
  <li>
    <input type="submit" id="p6" class="subbut"
      onclick="makeRequest('p6');"
      value="complexIntegrate(x^2/(x^4-a^2),x)" />
    <div id="ansp6"><div></div></div>
  </li>
</ul>

```

As with the real case, antiderivatives for most complex-valued functions cannot be expressed in terms of elementary functions.

```

<ul>
  <li>
    <input type="submit" id="p7" class="subbut"
      onclick="makeRequest('p7');"
      value="complexIntegrate(log(1+sqrt(a*x+b))/x,x)" />
    <div id="ansp7"><div></div></div>
  </li>
</ul>

```

Sometimes [integrate](dbopintegrate.xhtml) can involve symbolic algebraic numbers such as those returned by [rootOf](dboprootof.xhtml). To see how to work with these strange generated symbols (such as $\%a0$), see <axbook/section-8.3.xhtml#subsec-8.3.2> Using All Roots of a Polynomial.

Definite integration is the process of computing the area between the x-axis and the curve of a function $f(x)$. The fundamental theorem of calculus states that if f is continuous on an interval $a..b$ and such that $D(g,x)$ is equal to f , then the definite integral of f for x in the interval $a..b$ is equal to $g(b)-g(a)$.

The package

```

<a href="db.xhtml?RationalFunctionDefiniteIntegration">
RationalFunctionDefiniteIntegration</a>
provides the top-level definite integration operation,
<a href="dbopintegrate.xhtml">integrate</a>,
for integrating real-valued rational functions.

```

```

<ul>
  <li>
    <input type="submit" id="p8" class="subbut"
      onclick="makeRequest('p8');"
      value="integrate((x^4-3*x^2+6)/(x^6-5*x^4+5*x^2+4),x=1..2)" />
    <div id="ansp8"><div></div></div>
  </li>
</ul>

```

Axiom checks beforehand that the function you are integrating is defined on the interval $a..b$, and prints an error message if it finds that this is not the case, as in the following example:

```

<pre>
integrate(1/(x^2-2),x=1..2)

```

```

Error detected within library code:
Pole in path of integration

```

```

</pre>

```

When parameters are present in the function, the function may or may not be defined on the interval of integration.

If this is the case, Axiom issues a warning that a pole might lie in the path of integration, and does not compute the integral.

```
<ul>
  <li>
    <input type="submit" id="p9" class="subbut"
      onclick="makeRequest('p9');"
      value="integrate(1/(x^2-a),x=1..2)" />
    <div id="ansp9"><div></div></div>
  </li>
</ul>
```

If you know that you are using values of the parameter for which the function has no pole in the interval of integration, use the string "noPole" as a third argument to `integrate`.

The value here is, of course, incorrect if \sqrt{a} is between 1 and 2.

```
<ul>
  <li>
    <input type="submit" id="p10" class="subbut"
      onclick="makeRequest('p10');"
      value='integrate(1/(x^2-a),x=1..2,"noPole")' />
    <div id="ansp10"><div></div></div>
  </li>
</ul>
<page foot>
```

1.9.21 calseries.xhtml

```

<calseries.xhtml>≡
  <standard head>
    </head>
    <body>
      <page head>
        <div align="center">Working with Power Series</div>
        <hr/>

```

Axiom has very sophisticated facilities for working with power series. Infinite series are represented by a list of the coefficients that have already been determined, together with a function for computing the additional coefficients if needed. The system command that determines how many terms of a series is displayed is

```

<pre>
  )set streams calculate
</pre>

```

By default Axiom will display ten terms. Series can be created from expressions, from functions for the series coefficients, and from applications of operations on existing series. The most general function for creating a series is called [series](dbopseries.xhtml), although you can also use

[taylor](dboptaylor.xhtml),
[laurent](dboplaurent.xhtml), and
[puiseux](dboppuiseux.xhtml) in situations where you know what kind of exponents are involved.

For information about solving differential equations in terms of power series see

<axbook/section-8.10.xhtml#subsec-8.10.3>
 Power Series Solutions of Differential Equations

```

1.9.22 calseries1.xhtml

```

<calseries1.xhtml>≡
  <standard head>
    <script type="text/javascript">
      <handlefreevars>
      <axiom talker>
    </script>
  </head>
  <body onload="resetvars();">
    <page head>
      <div align="center">Creation of Power Series</div>
      <hr/>

```

This is the easiest way to create a power series. This tells Axiom that x is to be treated as a power series, so functions of x are again power series.

```

<ul>
  <li>
    <input type="submit" id="p1" class="subbut"
      onclick="makeRequest('p1');"
      value="x:=series 'x" />
    <div id="ansp1"><div></div></div>
  </li>
</ul>

```

We didn't say anything about the coefficients of the power series, so the coefficients are general expressions over the integers. This allows us to introduce denominators, symbolic constants, and other variables as needed. Here the coefficients are integers (note that the coefficients are the Fibonacci numbers).

```

<ul>
  <li>
    <input type="submit" id="p2" class="subbut"
      onclick="handleFree(['p1','p2']);"
      value="1/(1-x-x^2)" />
    <div id="ansp2"><div></div></div>
  </li>
</ul>

```

This series has coefficients that are rational numbers.

```

<ul>
  <li>
    <input type="submit" id="p3" class="subbut"
      onclick="handleFree(['p1','p3']);"
      value="sin(x)" />
    <div id="ansp3"><div></div></div>
  </li>
</ul>

```

When you enter this expression you introduce the symbolic constants $\sin(1)$

and $\cos(1)$.

```
<ul>
<li>
  <input type="submit" id="p4" class="subbut"
    onclick="handleFree(['p1','p4']);"
    value="sin(1+x)" />
  <div id="ansp4"><div></div></div>
</li>
</ul>
```

When you enter the expression the variable a appears in the resulting series expansion.

```
<ul>
<li>
  <input type="submit" id="p5" class="subbut"
    onclick="handleFree(['p1','p5']);"
    value="sin(a*x)" />
  <div id="ansp5"><div></div></div>
</li>
</ul>
```

You can also convert an expression into a series expansion. This expression creates the series expansion of $1/\log(v)$ about $v=1$. For details and more examples see

<axbook/section-8.9.xhtml#subsec-8.9.5>
 Converting to Power Series

```
<ul>
<li>
  <input type="submit" id="p6" class="subbut"
    onclick="makeRequest('p6');"
    value="series(1/log(v),v=1)" />
  <div id="ansp6"><div></div></div>
</li>
</ul>
```

You can create power series with more general coefficients. You normally accomplish this via a type declaration, see

<axbook/section-2.3.xhtml> Declarations

<axbook/section-8.9.xhtml#subsec-8.9.4>

Functions on Power Series for some warnings about working with declared series.

We declare that y is a one-variable Taylor series
 (<db.xhtml?UnivariateTaylorSeries> UTS is the abbreviation for
<db.xhtml?UnivariateTaylorSeries> UnivariateTaylorSeries in the
 variable z with <db.xhtml?Float> FLOAT (that is, floating-point)
 coefficients, centered about 0. Then, by assignment, we obtain the Taylor
 expansion of $\exp(z)$ with floating-point coefficients.

```
<ul>
```

```

<li>
  <input type="submit" id="p7" class="subbut"
    onclick="makeRequest('p7');"
    value="y:UTS(FLOAT,'z,0):=exp(z)" />
  <div id="ansp7"><div></div></div>
</li>
</ul>

```

You can also create a power series by giving an explicit formula for the n th coefficient. For details and more examples see

<axbook/section-8.9.xhtml#subsec-8.9.6>
 Power Series from Formulas

To create a series about $w=0$ whose n th Taylor coefficient is $1/n!$, you can evaluate this expression. This is the Taylor expansion of $\exp(w)$ at $w=0$.

```

<ul>
  <li>
    <input type="submit" id="p8" class="subbut"
      onclick="makeRequest('p8');"
      value="series(1/factorial(n),n,w=0)" />
    <div id="ansp8"><div></div></div>
  </li>
</ul>

```

<page foot>

1.9.23 calseries2.xhtml

```

<calseries2.xhtml>≡
  <standard head>
    <script type="text/javascript">
      <handlefreevars>
      <axiom talker>
    </script>
  </head>
  <body onload="resetvars();">
    <page head>
      <div align="center">Coefficients of Power Series</div>
      <hr/>

```

You can extract any coefficient from a power series -- even on that hasn't been computed yet. This is possible because in Axiom, infinite series are represented by a list of the coefficients that have already been determined, together with a function for computing additional coefficients. (This is known as lazy evaluation.) When you ask for a coefficient that hasn't yet been computed, Axiom computes whatever additional coefficients it needs and then stores them in the representation of the power series.

Here's an example of how to extract the coefficients of a power series.

```

<ul>
  <li>
    <input type="submit" id="p1" class="subbut"
      onclick="makeRequest('p1');"
      value="x:=series('x)" />
    <div id="ansp1"><div></div></div>
  </li>
  <li>
    <input type="submit" id="p2" class="subbut"
      onclick="handleFree(['p1','p2']);"
      value="y:=exp(x)*sin(x)" />
    <div id="ansp2"><div></div></div>
  </li>
</ul>

```

This coefficient is readily available

```

<ul>
  <li>
    <input type="submit" id="p3" class="subbut"
      onclick="handleFree(['p1','p2','p3']);"
      value="coefficient(y,6)" />
    <div id="ansp3"><div></div></div>
  </li>
</ul>

```

But let's get the fifteenth coefficient of y

```
<ul>
<li>
  <input type="submit" id="p4" class="subbut"
    onclick="handleFree(['p1','p2','p4']);"
    value="coefficient(y,15)" />
  <div id="ansp4"><div></div></div>
</li>
</ul>
```

If you look at y then you see that the coefficients up to order 15 have all been computed.

```
<ul>
<li>
  <input type="submit" id="p5" class="subbut"
    onclick="handleFree(['p1','p2','p4','p5']);"
    value="y" />
  <div id="ansp5"><div></div></div>
</li>
</ul>
```

<page foot>

1.9.24 calseries3.xhtml

```

<calseries3.xhtml>≡
  <standard head>
    <script type="text/javascript">

  </head>
  <body onload="resetvars();">
    <page head>
      <div align="center">Power Series Arithmetic</div>
      <hr/>

```

You can manipulate power series using the usual arithmetic operations

```

<a href="dbopplus.xhtml">+</a>,
<a href="dbopminus.xhtml">-</a>,
<a href="dbopstar.xhtml">*</a>, and
<a href="dbopdivide.xhtml">/</a>.

```

The results of these operations are also power series.

```

<ul>
  <li>
    <input type="submit" id="p1" class="subbut"
      onclick="makeRequest('p1');"
      value="x:=series 'x" />
    <div id="ansp1"><div></div></div>
  </li>
  <li>
    <input type="submit" id="p2" class="subbut"
      onclick="handleFree(['p1','p2']);"
      value="(3+x)/(1+7*x)" />
    <div id="ansp2"><div></div></div>
  </li>
</ul>

```

You can also compute $f(x)^g(x)$, where $f(x)$ and $g(x)$ are two power series.

```

<ul>
  <li>
    <input type="submit" id="p3" class="subbut"
      onclick="handleFree(['p1','p3']);"
      value="base:=1/(1-x)" />
    <div id="ansp3"><div></div></div>
  </li>
  <li>
    <input type="submit" id="p4" class="subbut"
      onclick="handleFree(['p1','p3','p4']);"
      value="expon:=x*base" />

```

```
<div id="ansp4"><div></div></div>
</li>
<li>
  <input type="submit" id="p5" class="subbut"
    onclick="handleFree(['p1','p3','p4','p5']);"
    value="base^expon" />
  <div id="ansp5"><div></div></div>
</li>
</ul>
<page foot>
```

1.9.25 calseries4.xhtml

```

<calseries4.xhtml>≡
  <standard head>
    <script type="text/javascript">
      <handlefreevars>
      <axiom talker>
    </script>
  </head>
  <body onload="resetvars();">
    <page head>
      <div align="center">Functions on Power Series</div>
      <hr/>

```

Once you have created a power series, you can apply transcendental functions (for example,

```

<a href="dbopexp.xhtml">exp</a>,
<a href="dboplog.xhtml">log</a>,
<a href="dbopsin.xhtml">sin</a>,
<a href="dboptan.xhtml">tan</a>,
<a href="dbopcosh.xhtml">cosh</a>, etc.) to it.

```

To demonstrate this, we first create the power series expansion of the rational function $x^2/(1-6x+x^2)$ about $x=0$.

```

<ul>
  <li>
    <input type="submit" id="p1" class="subbut"
      onclick="makeRequest('p1');"
      value="x:=series 'x" />
    <div id="ansp1"><div></div></div>
  </li>
  <li>
    <input type="submit" id="p2" class="subbut"
      onclick="handleFree(['p1','p2']);"
      value="rat:=x^2/(1-6*x+x^2)" />
    <div id="ansp2"><div></div></div>
  </li>
</ul>

```

If you want to compute the series expansion of $\sin(x^2/(1-6x+x^2))$ you simply compute the sine of rat.

```

<ul>
  <li>
    <input type="submit" id="p3" class="subbut"
      onclick="handleFree(['p1','p2','p3']);"
      value="sin(rat)" />
    <div id="ansp3"><div></div></div>
  </li>

```

```

</ul>
<hr/>
<b>Warning:</b> the type of the coefficients of a power series may affect
the kind of computations that you can do with that series. This can only
happen when you have made a declaration to specify a series domain with a
certain type of coefficient.
<hr/>
If you evaluate then you have declared that y is a one variable Taylor
series (<a href="db.xhtml?UnivariateTaylorSeries">UTS</a> is the abbreviation
for <a href="db.xhtml?UnivariateTaylorSeries">UnivariateTaylorSeries</a>) in
the variable y with <a href="dbfractioninteger.xhtml">FRAC INT</a> (that is,
fractions of integers) coefficients, centered about 0.
<ul>
<li>
<input type="submit" id="p4" class="subbut"
  onclick="makeRequest('p4');"
  value="y:UTS(FRAC INT,'y,0):='y" />
<div id="ansp4"><div></div></div>
</li>
</ul>
You can now compute certain power series in y, provided that these series
have rational coefficients.
<ul>
<li>
<input type="submit" id="p5" class="subbut"
  onclick="handleFree(['p4','p5']);"
  value="exp(y)" />
<div id="ansp5"><div></div></div>
</li>
</ul>
You can get examples of such series by applying transcendental functions
to series in y that have no constant terms.
<ul>
<li>
<input type="submit" id="p6" class="subbut"
  onclick="handleFree(['p4','p5','p6']);"
  value="tan(y^2)" />
<div id="ansp6"><div></div></div>
</li>
<li>
<input type="submit" id="p7" class="subbut"
  onclick="handleFree(['p4','p5','p7']);"
  value="cos(y+y^5)" />
<div id="ansp7"><div></div></div>
</li>
</ul>

```

Similarly, you can compute the logarithm of a power series with rational coefficients if the constant coefficient is 1.

```
<ul>
  <li>
    <input type="submit" id="p8" class="subbut"
      onclick="handleFree(['p4','p5','p8']);"
      value="log(1+sin(y))" />
    <div id="ansp8"><div></div></div>
  </li>
</ul>
```

If you wanted to apply, say, the operation [exp](dbopexp.xhtml) to a power series with a nonzero constant coefficient a_0 , then the constant coefficient of the result would be $\exp(a_0)$, which is not a rational number. Therefore, evaluating $\exp(2+\tan(y))$ would generate an error message.

If you want to compute the Taylor expansion of $\exp(2+\tan(y))$, you must ensure that the coefficient domain has an operation [exp](dbopexp.xhtml) defined for it. An example of such a domain is [Expression Integer](dbexpressioninteger.xhtml), the type of formal functional expressions over the integers. When working with coefficients of this type

```
<ul>
  <li>
    <input type="submit" id="p9" class="subbut"
      onclick="makeRequest('p9');"
      value="z:UTS(EXPR INT,'z,0):='z" />
    <div id="ansp9"><div></div></div>
  </li>
</ul>
```

this presents no problems.

```
<ul>
  <li>
    <input type="submit" id="p10" class="subbut"
      onclick="handleFree(['p9','p10']);"
      value="exp(2+tan(z))" />
    <div id="ansp10"><div></div></div>
  </li>
</ul>
```

Another way to create Taylor series whose coefficients are expressions over the integers is to use [taylor](dboptaylor.xhtml) which works similarly to [series](dbopseries.xhtml). This is equivalent to the previous computation, except that now we are using the variable w instead of z .

```
<ul>
  <li>
    <input type="submit" id="p11" class="subbut"
```

```
        onclick="makeRequest('p11');"
        value="w:=taylor 'w' />
    <div id="ansp11"><div></div></div>
</li>
<li>
    <input type="submit" id="p12" class="subbut"
        onclick="handleFree(['p11','p12']);"
        value="exp(2+tan(w))" />
    <div id="ansp12"><div></div></div>
</li>
</ul>
<page foot>
```

1.9.26 calseries5.xhtml

```

<calseries5.xhtml>≡
  <standard head>
    <script type="text/javascript">
      <handlefreevars>
      <axiom talker>
    </script>
  </head>
  <body onload="resetvars();">
    <page head>
      <div align="center">Converting to Power Series</div>
      <hr/>
      The <a href="db.xhtml?ExpressionToUnivariatePowerSeries">
      ExpressionToUnivariatePowerSeries</a> package provides operations for
      computing series expansions of functions.

```

Evaluate this to compute the Taylor expansion of $\sin x$ about $x=0$. The first argument, $\sin(x)$, specifies the function whose series expansion is to be computed and the second argument, $x=0$, specifies that the series is to be expanded in powers of $(x-0)$, that is, in powers of x .

```

<ul>
  <li>
    <input type="submit" id="p1" class="subbut"
      onclick="makeRequest('p1');"
      value="taylor(sin(x),x=0)" />
    <div id="ansp1"><div></div></div>
  </li>
</ul>

```

Here is the Taylor expansion of $\sin x$ about $x=\pi/6$:

```

<ul>
  <li>
    <input type="submit" id="p2" class="subbut"
      onclick="makeRequest('p2');"
      value="taylor(sin(x),x=%pi/6)" />
    <div id="ansp2"><div></div></div>
  </li>
</ul>

```

The function to be expanded into a series may have variables other than the series variable. For example, we may expand $\tan(x*y)$ as a Taylor series in x .

```

<ul>
  <li>
    <input type="submit" id="p3" class="subbut"
      onclick="makeRequest('p3');"
      value="taylor(tan(x*y),x=0)" />
    <div id="ansp3"><div></div></div>

```

```

</li>
</ul>
or as a Taylor series in y.
<ul>
<li>
  <input type="submit" id="p4" class="subbut"
    onclick="makeRequest('p4');"
    value="taylor(tan(x*y),y=0)" />
  <div id="ansp4"><div></div></div>
</li>
</ul>

```

A more interesting function is $(t * e^{(x*t)}) / (e^t - 1)$. When we expand this function as a Taylor series in t the n th order coefficient is the n th Bernoulli polynomial divided by $n!$.

```

<ul>
<li>
  <input type="submit" id="p5" class="subbut"
    onclick="makeRequest('p5');"
    value="bern:=taylor(t*exp(x*t)/(exp(t)-1),t=0)" />
  <div id="ansp5"><div></div></div>
</li>
</ul>

```

Therefore, this and the next expression produce the same result.

```

<ul>
<li>
  <input type="submit" id="p6" class="subbut"
    onclick="handleFree(['p5','p6']);"
    value="factorial(6)*coefficient(bern,6)" />
  <div id="ansp6"><div></div></div>
</li>
<li>
  <input type="submit" id="p7" class="subbut"
    onclick="handleFree(['p6','p7']);"
    value="bernoulliB(6,x)" />
  <div id="ansp7"><div></div></div>
</li>
</ul>

```

Technically, a series with terms of negative degree is not considered to be a Taylor series, but rather a Laurent series. If you try to compute a Taylor series expansion of $x/\log(x)$ at $x=1$ via `taylor(x/log(x),x=1)` you get an error message. The reason is that the function has a pole at $x=1$, meaning that its series expansion about this point has terms of negative degree. A series with finitely many terms of negative degree is called a Laurent series. You get the desired series expansion by issuing this.

```

<ul>
<li>

```

```

<div></div></div>
</li>
</ul>

```

Similarly, a series with terms of fractional degree is neither a Taylor series nor a Laurent series. Such a series is called a Puiseux series. The expression `laurent(sqrt(sec(x)),x=3*%pi/2)` results in an error message because the series expansion about this point has terms of fractional degree. However, this command produces what you want.

```

<ul>
<li>
<div></div></div>
</li>
</ul>

```

Finally, consider the case of functions that do not have Puiseux expansions about certain points. An example of this is x^x about $x=0$. `puiseux(x^x,x=0)` produces an error message because of the type of singularity of the function at $x=0$. The general function `series` can be used in this case. Notice that the series returned is not, strictly speaking, a power series because of the $\log(x)$ in the expansion.

```

<ul>
<li>
<div></div></div>
</li>
</ul>
<hr/>

```

The operation `series` returns the most general type of infinite series. The user who is not interested in distinguishing between various types of infinite series may wish to use this operation exclusively.

```
<hr/>
```

```

      <axiom talker>
    </script>
  </head>
  <body onload="resetvars();">
    <page head>
      <div align="center">Power Series from Formulas</div>
      <hr/>
      The <a href="db.xhtml?GenerateUnivariatePowerSeries">
        GenerateUnivariatePowerSeries</a> package enables you to create power series
        from explicit formulas for their nth coefficients. In what follows, we
        construct series expansions for certain transcendental functions by giving
        formulas for their coefficients. You can also compute such series
        expansions directly by simply specifying the function and the point about
        which the series is to be expanded. See
        <a href="axbook/section-8.9.xhtml#subsec-8.9.5">
          Converting to Power Series</a> for more information.

```

Consider the Taylor expansion of e^x about $x=0$:

```

<pre>
  %e^x = 1 + x + x^2/2 + x^3/6 + ...
        = sum from n=0 to n=%infinity of x^n/n!

```

```

</pre>

```

The nth Taylor coefficient is $1/n!$. This is how to create this series in Axiom.

```

<ul>
  <li>
    <input type="submit" id="p1" class="subbut"
      onclick="makeRequest('p1');"
      value="series(n+->1/factorial(n),x=0)" />
    <div id="ansp1"><div></div></div>
  </li>
</ul>

```

The first argument specifies the formula for the nth coefficient by giving a function that maps n to $1/n!$. The second argument specifies that the series is to be expanded in powers of $(x-0)$, that is, in powers of x . Since we did not specify an initial degree, the first term in the series was the term of degree 0 (the constant term). Note that the formula was given as an anonymous function. These are discussed in

Anonymous Functions

Consider the Taylor expansion of $\log x$ about $x=1$:

```
<pre>
log x = (x-1) - (x-1)^2/2 + (x-1)^3/3 - ...
      = sum from n=1 to n=%infinity of (-1)^(n-1) (x-1)^n/n
</pre>
```

If you were to evaluate the expression `series(n+>(-1)^(n-1)/n,x=1)` you would get an error message because Axiom would try to calculate a term of degree $n=1, \dots$ are to be computed.

```
<ul>
<li>
  <input type="submit" id="p2" class="subbut"
    onclick="makeRequest('p2');"
    value="series(n+>(-1)^(n-1)/n,x=1,1..)" />
  <div id="ansp2"><div></div></div>
</li>
</ul>
```

Next consider the Taylor expansion of an odd function, say, $\sin(x)$:

```
<pre>
sin x = x = x^2/3! + x^5/5! - ...
</pre>
```

Here every other coefficient is zero and we would like to give an explicit formula only for the odd Taylor coefficients. This is one way to do it. The third argument, `1..`, specifies that the first term to be computed is the term of degree 1. The fourth argument, `2`, specifies that we increment by 2 to find the degrees of subsequent terms, that is, the next term is of degree $1+2$, the next of degree $1+2+2$, etc.

```
<ul>
<li>
  <input type="submit" id="p3" class="subbut"
    onclick="makeRequest('p3');"
    value="series(n+>(-1)^((n-1)/2)/factorial(n),x=0,1..,2)" />
  <div id="ansp3"><div></div></div>
</li>
</ul>
```

The initial degree and the increment do not have to be integers. For example, this expression produces a series expansion of $\sin(x^{1/3})$.

```
<ul>
<li>
  <input type="submit" id="p4" class="subbut"
    onclick="makeRequest('p4');"
    value="series(n+>(-1)^((3*n-1)/2)/factorial(3*n),x=0,1/3..,2/3)" />
  <div id="ansp4"><div></div></div>
</li>
</ul>
```

While the increment must be positive, the initial degree may be negative. This yields the Laurent expansion of $\csc(x)$ at $x=0$.

```

<ul>
<li>
  <input type="submit" id="p5" class="subbut"
    onclick="makeRequest('p5');"
    value="cscx:=series(n+>(-1)^((n-1)/2)*2*(2^n-1)*bernoulli(numer(n+1))/factorial(n+1),x=0,-
  <div id="ansp5"><div></div></div>
</li>
</ul>

```

Of course, the reciprocal of this power series is the Taylor expansion of $\sin(x)$.

```

<ul>
<li>
  <input type="submit" id="p6" class="subbut"
    onclick="handleFree(['p5','p6']);"
    value="1/cscx" />
  <div id="ansp6"><div></div></div>
</li>
</ul>

```

As a final example, here is the Taylor expansion of $\arcsin(x)$ about $x=0$.

```

<ul>
<li>
  <input type="submit" id="p7" class="subbut"
    onclick="makeRequest('p7');"
    value="asinx:=series(n+>binomial(n-1,(n-1)/2)/(n*2^(n-1)),x=0,1..,2)" />
  <div id="ansp7"><div></div></div>
</li>
</ul>

```

When we compute the sine of this series, we get x (in the sense that all higher terms computed so far are zero).

```

<ul>
<li>
  <input type="submit" id="p8" class="subbut"
    onclick="handleFree(['p7','p8']);"
    value="sin(asinx)" />
  <div id="ansp8"><div></div></div>
</li>
</ul>

```

As we discussed in

<calseries5.xhtml>>Converting to Power Series, you can also use the operations

<dboptaylor.xhtml>>taylor,

<dboplaurent.xhtml>>laurent, and

<dboppuiseux.xhtml>>puiseux, instead of

<dbopseries.xhtml>>series if you know ahead of time what kind of exponents a series has. You can't go wrong with

<dbopseries.xhtml>>series though.

<page foot>

1.9.28 calseries7.xhtml

```

<calseries7.xhtml>≡
  <standard head>
    <script type="text/javascript">
      <handlefreevars>

  </head>
  <body onload="resetvars();">
    <page head>
      <div align="center">Substituting Numerical Values in Power Series</div>
      <hr/>

```

Use `eval` to substitute a numerical value for a variable in a power series. For example, here's a way to obtain numerical approximations of e from the Taylor series expansion of $\exp(x)$.

First you create the desired Taylor expansion.

```

<ul>
  <li>
    <input type="submit" id="p1" class="subbut"
      onclick="makeRequest('p1');"
      value="f:=taylor(exp(x))" />
    <div id="ansp1"><div></div></div>
  </li>
</ul>

```

Then you evaluate the series at the value 1.0. The result is a sequence of the partial sums.

```

<ul>
  <li>
    <input type="submit" id="p2" class="subbut"
      onclick="handleFree(['p1','p2']);"
      value="eval(f,1.0)" />
    <div id="ansp2"><div></div></div>
  </li>
</ul>
<page foot>

```

1.9.29 calseries8.xhtml

```

<calseries8.xhtml>≡
  <standard head>
    <script type="text/javascript">
      <handlefreevars>
      <axiom talker>
    </script>
  </head>
  <body onload="resetvars();">
    <page head>
      <div align="center">Example: Bernoulli Polynomials and Sums of Powers</div>
      <hr/>

```

Axiom provides operations for computing definite and indefinite sums.

You can compute the sum of the first ten fourth powers by evaluating this. This creates a list whose entries are m^4 as m ranges from 1 to 10, and then computes the sum of the entries of that list.

```

<ul>
  <li>
    <input type="submit" id="p1" class="subbut"
      onclick="makeRequest('p1');"
      value="reduce(+,[m^4 for m in 1..10])" />
    <div id="ansp1"><div></div></div>
  </li>
</ul>

```

You can also compute a formula for the sum of the first k fourth powers, where k is an unspecified positive integer.

```

<ul>
  <li>
    <input type="submit" id="p2" class="subbut"
      onclick="makeRequest('p2');"
      value="sum4:=sum(m^4,m=1..k)" />
    <div id="ansp2"><div></div></div>
  </li>
</ul>

```

This formula is valid for any positive integer k . For instance, if we replace k by 10, we obtain the number we computed earlier.

```

<ul>
  <li>
    <input type="submit" id="p3" class="subbut"
      onclick="handleFree(['p2','p3']);"
      value="eval(sum4,k=10)" />
    <div id="ansp3"><div></div></div>
  </li>
</ul>

```

You can compute a formula for the sum of the first k n th powers in a similar fashion. Just replace the 4 in the definition of `sum4` by any expression not involving k . Axiom computes these formulas using Bernoulli polynomials; we use the rest of this section to describe this method.

First consider this function of t and x .

```
<ul>
  <li>
    <input type="submit" id="p4" class="subbut"
      onclick="makeRequest('p4');"
      value="f:=t*exp(x*t)/(exp(t)-1)" />
    <div id="ansp4"><div></div></div>
  </li>
</ul>
```

Since the expressions involved get quite large, we tell Axiom to show us only terms of degree up to 5.

```
<ul>
  <li>
    <input type="submit" id="p5" class="noresult"
      onclick="makeRequest('p5');"
      value=")set streams calculate 5" />
    <div id="ansp5"><div></div></div>
  </li>
</ul>
```

If we look at the Taylor expansion of $f(x,t)$ about $t=0$, we see that the coefficients of the powers of t are polynomials in x .

```
<ul>
  <li>
    <input type="submit" id="p6" class="subbut"
      onclick="handleFree(['p4','p5','p6']);"
      value="ff:=taylor(f,t=0)" />
    <div id="ansp6"><div></div></div>
  </li>
</ul>
```

In fact, the n th coefficient in this series is essentially the n th Bernoulli polynomial: the n th coefficient of the series is $1/n! \cdot B_n(x)$, where $B_n(x)$ is the n th Bernoulli polynomial. Thus, to obtain the n th Bernoulli polynomial, we multiply the n th coefficient of the series `ff` by $n!$. For example, the sixth Bernoulli polynomial is this.

```
<ul>
  <li>
    <input type="submit" id="p7" class="subbut"
      onclick="handleFree(['p4','p5','p6','p7']);"
      value="factorial(6)*coefficient(ff,6)" />
    <div id="ansp7"><div></div></div>
  </li>
```

We derive some properties of the function $f(x,t)$. First we compute $f(x+1,t)-f(x,t)$.

```
<input type="submit" id="p8" class="subbut"
  onclick="handleFree(['p4','p8']);"
  value="g:=eval(f,x=x+1)-f" />
<div id="ansp8"><div></div></div>
```

If we normalize g , we see that it has a particularly simple form.

```
<input type="submit" id="p9" class="subbut"
  onclick="handleFree(['p4','p8','p9']);"
  value="normalize(g)" />
<div id="ansp9"><div></div></div>
```

From this it follows that the n th coefficient in the Taylor expansion of $g(x,t)$ at $t=0$ is $1/(n-1)! \cdot x^{(n-1)}$. If you want to check this, evaluate the next expression.

```
<input type="submit" id="p10" class="subbut"
  onclick="handleFree(['p4','p5','p8','p9','p10']);"
  value="taylor(g,t=0)" />
<div id="ansp10"><div></div></div>
```

However, since

<pre>

```
g(x,t)=f(x+1,t)-f(x,t)
```

</pre>

it follows that the n th coefficient is

<pre>

```
1/n! * (Bn(x+1) - Bn(x))
```

</pre>

Equating coefficients, we see that

<pre>

```
1/(n-1)! * x^(n-1) = 1/n! * (Bn(x+1) - Bn(x))
```

</pre>

and, therefore

<pre>

$$x^{(n-1)} = 1/n * (B_n(x+1) - B_n(x))$$

</pre>

Let's apply this formula repeatedly, letting x vary between two integers a and b, with $a \leq b$:

<pre>

$$\begin{aligned} a^{(n-1)} &= 1/n * (B_n(a+1) - B_n(a)) \\ (a+1)^{(n-1)} &= 1/n * (B_n(a+2) - B_n(a+1)) \\ (a+2)^{(n-1)} &= 1/n * (B_n(a+3) - B_n(a+2)) \\ &\vdots \\ (b-1)^{(n-1)} &= 1/n * (B_n(b) - B_n(b-1)) \\ b^{(n-1)} &= 1/n * (B_n(b+1) - B_n(b)) \end{aligned}$$

</pre>

When we add these equations we find that the sum of the left-hand sides is

<pre>

$$\text{sum}(m=a..b, m^{(n-1)})$$

</pre>

the sum of the (n-1)-st powers from a to b. The sum of the right-hand sides is a "telescoping series". After cancellation, the sum is simply

<pre>

$$1/n * (B_n(b+1) - B_n(a))$$

</pre>

Replacing n by n+1, we have shown that

<pre>

$$\text{sum}(m=a..b, m^n) = 1/(n+1) * (B_{n+1}(b+1) - B_{n+1}(a))$$

</pre>

Let's use this to obtain the formula for the sum of fourth powers. First we obtain the Bernoulli polynomial B5.

```
<input type="submit" id="p11" class="subbut"
  onclick="handleFree(['p4','p5','p6','p11']);"
  value="B5:=factorial(5)*coefficient(ff,5)" />
<div id="ansp11"><div></div></div>
```

To find the sum of the first k 4th powers, we multiply 1/5 by B5(k+1)-B5(1)

```
<input type="submit" id="p12" class="subbut"
  onclick="handleFree(['p4','p5','p6','p11','p12']);"
  value="1/5*(eval(B5,x=k+1)-eval(B5,x=1))" />
```

```

    <div id="ansp12"><div></div></div>
  </li>
</ul>
This is the same formula that we obtained via sum(m^4,m=1..k)
<ul>
  <li>
    <input type="submit" id="p13" class="subbut"
      onclick="handleFree(['p2','p13']);"
      value="sum4" />
    <div id="ansp13"><div></div></div>
  </li>
</ul>

```

At this point you may want to do the same computation, but with an exponent other than 4. For example, you might try to find a formula for the sum of the first k 20th powers.

      <input type="submit" id="p4" class="subbut"
        onclick="makeRequest('p4');"
        value="r:=3/7::Float" />

```

```

    <div id="ansp4"><div></div></div>
  </li>
  <li>
    <input type="submit" id="p5" class="subbut"
      onclick="handleFree(['p4','p5']);"
      value="r::Fraction Integer" />
    <div id="ansp5"><div></div></div>
  </li>
</ul>
This conversion cannot be performed: use
<a href="dboptruncate.xhtml">truncate</a> or
<a href="dbopround.xhtml">round</a> if that is what you intend.
<ul>
  <li>
    <input type="submit" id="p6" class="subbut"
      onclick="handleFree(['p4','p6']);"
      value="r::Integer" />
    <div id="ansp6"><div></div></div>
  </li>
</ul>
The operations
<a href="dboptruncate.xhtml">truncate</a> and
<a href="dbopround.xhtml">round</a> truncate ...
<ul>
  <li>
    <input type="submit" id="p7" class="subbut"
      onclick="makeRequest('p7');"
      value="truncate 3.6" />
    <div id="ansp7"><div></div></div>
  </li>
</ul>
and round to the nearest integral <a href="db.xhtml?Float">Float</a>
respectively.
<ul>
  <li>
    <input type="submit" id="p8" class="subbut"
      onclick="makeRequest('p8');"
      value="round 3.6" />
    <div id="ansp8"><div></div></div>
  </li>
  <li>
    <input type="submit" id="p9" class="subbut"
      onclick="makeRequest('p9');"
      value="truncate(-3.6)" />
    <div id="ansp9"><div></div></div>
  </li>

```

```

<li>
  <input type="submit" id="p10" class="subbut"
    onclick="makeRequest('p10');"
    value="round(-3.6)" />
  <div id="ansp10"><div></div></div>
</li>
</ul>

```

The operation [fractionPart](dbopfractionpart.xhtml) computes the fractional part of x , that is, $x - \text{truncate } x$.

```

<ul>
<li>
  <input type="submit" id="p11" class="subbut"
    onclick="makeRequest('p11');"
    value="fractionPart 3.6" />
  <div id="ansp11"><div></div></div>
</li>
</ul>

```

The operation [digits](dbopdigits.xhtml) allows the user to set the precision. It returns the previous value it was using.

```

<ul>
<li>
  <input type="submit" id="p12" class="subbut"
    onclick="makeRequest('p12');"
    value="digits 40" />
  <div id="ansp12"><div></div></div>
</li>
<li>
  <input type="submit" id="p13" class="subbut"
    onclick="makeRequest('p13');"
    value="sqrt 0.2" />
  <div id="ansp13"><div></div></div>
</li>
<li>
  <input type="submit" id="p14" class="subbut"
    onclick="makeRequest('p14');"
    value="pi()$Float" />
  <div id="ansp14"><div></div></div>
</li>
</ul>

```

The precision is only limited by the computer memory available. Calculations at 500 or more digits of precision are not difficult.

```

<ul>
<li>
  <input type="submit" id="p15" class="subbut"
    onclick="makeRequest('p15');"
    value="digits 500" />

```

```

    <div id="ansp15"><div></div></div>
  </li>
  <li>
    <input type="submit" id="p16" class="subbut"
      onclick="makeRequest('p16');"
      value="pi()$Float" />
    <div id="ansp16"><div></div></div>
  </li>
</ul>
Reset <a href="dbopdigits.xhtml">digits</a> to its default value.
<ul>
  <li>
    <input type="submit" id="p17" class="subbut"
      onclick="makeRequest('p17');"
      value="digits 20" />
    <div id="ansp17"><div></div></div>
  </li>
</ul>

```

Numbers of type `Float` are represented as a record of two integers, namely, the mantissa and the exponent where the base of the exponent is binary. That is, the floating point number of the binary. That is, the floating point number (m,e) represents the number $m \cdot 2^e$. A consequence of using a binary base is that decimal numbers can not, in general, be represented exactly.

      <page head>
        <center>
          <h2>RCM3720 Cryptography, Network and Computer Security</h2>
          <h3>Laboratory Class 1: Introduction to Axiom</h3>
        </center>
        <hr/>

        <b>Numbers and arithmetic</b>

        <ul>
          <li> You can treat Axiom like a glorified calculator. Enter the following:
            <ul>
              <li> <span class="cmd">3+5</span></li>
              <li> <span class="cmd">5*7</span></li>
              <li> <span class="cmd">2^3/3^5</span></li>
              <li> <span class="cmd">(3^4)^5</span></li>
              <li> <span class="cmd">3^(4^5)</span></li>
            </ul>
          </li>
          <li> What happens if you enter the last command without the brackets?</li>

          <li> To obtain the factorial <tt>n!</tt>, use the Axiom command
            <tt>factorial</tt>:
            <ul>
              <li> <span class="cmd">factorial(10)</span></li>
            </ul>
          </li>
          <li> By trial and error, find the smallest number whose factorial
            ends in six zeros.
          </li>
        </ul>

        <b>Lists</b>

        <ul>
          <li> Assignment is done using "<tt>:=</tt>"
            where the <i>colon-equals</i> symbols are
            used for assigning a particular object to a variable.
            <ul>
              <li> <span class="cmd">var:=3</span></li>
            </ul>
          </li>
        </ul>
      </body>
    </standard head>
  </cryptoclass1.xhtml>

```

```

    </ul>
</li>
<li> Lists are created using square brackets;
    <ul>
        <li> <span class="cmd">mylist1:=[k^2 for k in 1..10]</span></li>
    </ul>
</li>
<li> We can operate on all elements of a list using the
    <tt>reduce</tt> command:
    <ul>
        <li> <span class="cmd">reduce(+,mylist1)</span></li>
        <li> <span class="cmd">reduce(*,mylist2)</span></li>
    </ul>
</li>
<li> Of course, these could be done as single commands:
    <ul>
        <li> <span class="cmd">reduce(+,[k^2 for k in 1..10])</span></li>
        <li> <span class="cmd">reduce(*,[1/j for j in 5..15])</span></li>
    </ul>
</li>
<li> Notice how the last result is given as a single large fraction. To
    obtain a decimal result we can do either of two things:
    <ol>
        <li> Convert the output to be of type ‘‘Float’’:
            <ul>
                <li> <span class="cmd">reduce(*,[1/j for j in 5..15]):Float</span></li>
                <li> Two colons can be used to change the type of an object.</li>
            </ul>
        </li>
        <li> Use floats in the initial command:
            <ul>
                <li> <span class="cmd">reduce(*,[1.0/j for j in 5..15])</span></li>
            </ul>
        </li>
    </ol>
</li>
<li> Using lists, add up the first 1000 integers.</li>

<li> By trial and error, find the smallest number <i>n</i> for which
    the sum of the first <i>n</i> reciprocals is bigger than 8.
</li>
<li> We can also add numbers by using the <tt>sum</tt> function; here’s how
    to add the first 100 reciprocals:
    <ul>
        <li> <span class="cmd">sum(1.0/k,k = 1..100)</span></li>
    </ul>

```

```

</li>
</ul>

<b>Functions and maps</b>

<ul>
<li> We shall create a simple function, and apply it to <tt>mylist1</tt> from
    above:
    <ul>
      <li> <span class="cmd">f(x) == x-2</span></li>
      <li> <span class="cmd">map(f,mylist1)</span></li>
    </ul>
</li>
<li> Supposing we want to subtract 2 from every element of a list without
    having to create a function first. In this case we can use the
    "mapping" symbols:
    <ul>
      <li> <span class="cmd">map(x +-> x-2,mylist1)</span></li>
    </ul>
</li>
<li> Create a list called <tt>nums</tt> containing all the integers from 1
    to 100. Now we shall create a simple function <tt>f(x)</tt> which
    returns <tt>x</tt> if it is prime, and 0 otherwise. The Axiom
    function <tt>prime?</tt> tests for primality:
    <ul>
      <li> <span class="cmd">f(x)==if prime?(x) then x else 0</span></li>
    </ul>
</li>
<li> Now apply this function <tt>f</tt> to <tt>nums</tt>.
    Remove all the zeros:
    <i>(% refers to the output of the last command.)</i>
    <ul>
      <li> <span class="cmd">remove(0,%)</span></li>
    </ul>
</li>
<li> and determine how many primes there are, using the hash symbol #
    which can be used to count the number of elements in a list:
    <ul>
      <li> <span class="cmd">#%</span></li>
    </ul>
</li>
<li> These last commands can be done as a single command:
    <ul>
      <li> <span class="cmd">#remove(0,map(f,nums))</span></li>
    </ul>
</li>

```

```

<li> Use the last command to create a function called <tt>numprimes</tt>
      which will count the number of primes below any given integer.
</li>
<li> How many primes are there less than 1000? Less than 10000?</li>

<li> Alternatively, we can list all the primes below 100 by creating our
      list using the "such that" operator---a vertical stroke:
      <ul>
        <li> <span class="cmd">[k for k in 1..100 | prime?(k)]</span></li>
      </ul>
</li>
<li> or we could just return the length of the list:
      <ul>
        <li> <span class="cmd">#[k for k in 1..100 | prime?(k)]</span></li>
      </ul>
</li>
<li> Use this approach to create a function called <tt>numprimes2</tt>
      which will count the number of primes below any given integer.
</li>
<li>How many primes are there less than 2000? Less than 15000?</li>
</ul>

<b>Housekeeping</b><br>

```

Axiom contains many commands for managing your workspace and your environment; such commands are all prefixed with a right parenthesis.

```

<ul>
  <li> Sometimes you need to clear a variable, say a variable <tt>x</tt>:
    <ul>
      <li> <span class="cmd">)<clear properties x</span></li>
    </ul>
  </li>
  <li> Most commands of this sort can be abbreviated using their
        first two letters:
    <ul>
      <li> <span class="cmd">)<cl pr x</span></li>
    </ul>
  </li>
  <li> To clean out everything:
    <ul>
      <li> <span class="cmd">)<cl all</span></li>
    </ul>
  </li>
  <li> To see what variables you've accumulated over your work:
    <ul>

```

```

    <li> <span class="cmd">)display names</span></li>
    <li> <i>or abbreviated as</i> )d n</li>
  </ul>
</li>
<li> You may have noticed earlier that Axiom poured out lots
      of messages when it first "got going". These can be turned off:
    <ul>
      <li> <span class="cmd">)set messages autoload off</span></li>
    </ul>
</li>
<li> Note here that if you just type in "<tt>)set</tt>" or its abbreviation
      "<tt>)se</tt>", you'll be presented with the list of all the possible
      options. Likewise "<tt>)se me</tt>" lists all possible options for
      messages, and so on.
</li>
<li> Can you find the command which turns on a time function,
      so gives the time to compute each command?
</li>
<li> The command "<tt>)summary</tt>" gives a quick summary of these
      commands.
</li>
<li> To quit Axiom, type
    <ul>
      <li> <span class="cmd">)quit</span></li>
    </ul>
</li>
<li> or its one letter abbreviation "<tt>)q</tt>", followed by <tt>y</tt> to
      confirm.
</li>
</ul>
<page foot>

1.9.36 cryptoclass2.xhtml

```

<cryptoclass2.xhtml>≡
  <standard head>
  </head>
  <body>
    <page head>
    <center>
      <h2>RCM3720 Cryptography, Network and Computer Security</h2>
      <h3>Laboratory Class 2: Strings and Values</h3>
    </center>
    <hr/>

    <b>Characters and Strings</b>

    <ul>
      <li> All printable characters have a fixed ASCII value; some of which are:
      <br/>
      <pre>
          Character |  A   B   Y   Z   a   b   y   z
          -----+-----
          ASCII Value | 65  66  89  90  97  98 121 122
                   |
          Character |  0   1   8   9   ,   -   .   /
          -----+-----
          ASCII Value | 48  49  56  57  44  45  46  47
      </pre>
      </li>
      <li> To obtain values 0 to 25 for A to Z, we need to subtract 65 from
          the ASCII values.
      </li>
      <li> In Axiom, the <tt>ord</tt> command gives the ASCII value of a
          character. Create a string such as:
          <ul>
            <li> <span class="cmd">str:="THISISASTRING"</span></li>
          </ul>
      </li>
      <li> A string can be turned into a list of characters using <tt>members</tt>:
          <ul>
            <li> <span class="cmd">members(str)</span></li>
          </ul>
      </li>
      <li> This means a string can be turned into a list of ASCII values by
          mapping the <tt>ord</tt> function onto the list of members:
          <ul>
            <li> <span class="cmd">map(ord,members(str))</span></li>
          </ul>
      </li>
    </ul>
  </body>
</cryptoclass2.xhtml>

```

```

    </ul>
</li>
<li> To obtain values in the 0--25 range, try using an unnamed function:
    <ul>
      <li> <span class="cmd">strn:=map(x +-> ord(x)-65,members(str))</span></li>
    </ul>
</li>
<li> Use this last command to create a function <tt>str2lst</tt> which will
    take a string (assumed to be of capital letters, with no spaces or
    punctuation), and return a list of values between 0 and 25.
</li>
<li> To go the other way, we first need to add 65 to all elements of
    <tt>strn</tt>:
    <ul>
      <li> <span class="cmd">map(x +-> x+65,strn)</span></li>
    </ul>
</li>
<li> Turn this into characters with <tt>char</tt>:
    <ul>
      <li> <span class="cmd">map(char,%)</span></li>
    </ul>
</li>
<li> These can be done as a single command:
    <ul>
      <li> <span class="cmd">map(x +-> char(x+65),strn)</span></li>
    </ul>
</li>
<li> To put them all together as a single string we can concatenate them
    with the <tt>concat</tt> function from the <tt>String</tt> domain:
    <ul>
      <li> <span class="cmd">concat(%)$String</span></li>
    </ul>
</li>
<li> In one line:
    <ul>
      <li> <span class="cmd">concat(map(x +-> char(x+65),strn))$String</span></li>
    </ul>
</li>
<li> Alternatively, we could convert the characters to type <tt>String</tt>
    before concatenation:
    <ul>
      <li>
        <span class="cmd">
          concat(map(x +-> char(x+65)::String,strn))
        </span>
      </li>
    </ul>

```

```

    </ul>
</li>
<li> Use either version of this last command to create a function
    <tt>lst2str</tt> which will take a list of values between 0 and 25 and
    return a string.
</li>
<li> Create a text file in one of your private directories called
    <tt>my3720.input</tt> and copy your <tt>str2lst</tt> and
    <tt>lst2str</tt> functions to it.
</li>
<li> You can read command line input from a file with the extension
    <tt>.input</tt> using the <tt>read</tt> command:
    <ul>
        <li> <span class="cmd"><tt>read my3720</tt></span></li>
    </ul>
</li>
<li> The Caesar cipher can be implemented by the following three steps:
    <ol>
        <li> Turn the string into a list,</li>
        <li> Add 3 to every number in the list,</li>
        <li> Turn this new list back into a string.</li>
    </ol>
</li>
<li> To ensure that step (2) remains in the 0--25 range, we need to use the
    <tt>rem</tt> function. These can all be put together as:
    <ul>
        <li>
            <span class="cmd">
                caesar(str) == lst2str(map(x +-> (x+3) rem 26, str2lst(str)))
            </span>
        </li>
    </ul>
</li>
<li> Try this out on a few strings of your choice.</li>

<li> By replacing the "<tt>+3</tt>" in the <tt>caesar</tt> function with
    "<tt>+n</tt>" create a new function called <tt>trans(str,n)</tt> which
    implements a general translation cipher.
</li>
<li> Test it out; these two commands should produce the same results.
    <ul>
        <li> <span class="cmd"><tt>caesar("MYSTRING")</tt></span></li>
        <li> <span class="cmd"><tt>trans("MYSTRING",3)</tt></span></li>
    </ul>
</li>
<li> If you like, add the <tt>caesar</tt> and <tt>trans</tt> functions to

```

```

    your <tt>my3720.input</tt> file.
</li>
<li> Test your <tt>trans</tt> function out on a few other strings and
    translation values.
</li>
<li> The <tt>ROT13</tt> cipher is used in Usenet postings to hide information
    which might be considered offensive. It is a translation cipher with a
    shift of 13. Since 13 is half of 26, this means that encrytion and
    decryption are exactly the same. Apply <tt>ROT13</tt> to:
    <ul>
        <li> GUVFVFNIRELRFREVBHFOHFVARFF</li>
    </ul>
</li>
<li> Consider this string which has been produced with a translation cipher.
    To decrypt it, simply apply all possible shifts until you obtain
    understandable text.
    <ul>
        <li> IUDTCUQBBOEKHCEDUO</li>
    </ul>
</li>
<li> To apply all the possible shifts do:
    <ol>
        <li> <span class="cmd">ct:="IUDTCUQBBOEKHCEDUO"</span></li>
        <li> <span class="cmd">for i in 1..26 repeat output trans(ct,i)</span></li>
    </ol>
</li>
<li> What is the plaintext?</li>
</ul>
<page foot>

  <body>
    <page head>
    <center>
      <h2>RCM3720 Cryptography, Network and Computer Security</h2>
      <h3>Laboratory Class 3: Number Theory</h3>
    </center>
    <hr/>

    <ul>

      <li> Check out the commands <tt>gcd</tt> and <tt>factor</tt>, and test them
        on different numbers, small and large.
      </li>
      <li> Axiom provides a few useful commands for taking apart the factors of an
        object:
        <ul>
          <li> <span class="cmd">n:=5040</span></li>
          <li> <span class="cmd">f:=factor(n)</span></li>
          <li> <span class="cmd">numf:=numberOfFactors(f)</span></li>
          <li> <span class="cmd">fs:=[nthFactor(f,i) for i in 1..numf]</span></li>
          <li> <span class="cmd">es:=[nthExponent(f,i) for i in 1..numf]</span></li>
          <li> <span class="cmd">reduce(*,[fs.i^es.i for i in 1..numf])</span></li>
        </ul>
      </li>
      <li> The last command simply multiplies all the factors to their powers.</li>

      <li> Check out the commands <tt>prime?</tt>, <tt>nextPrime</tt> and
        <tt>prevPrime</tt>.
      </li>
      <li> To compute the <tt>i</tt>-th prime, we can construct a <i>stream</i>
        (an infinite list) in Axiom:
        <ul>
          <li>
            <span class="cmd">
              primes:Stream Integer:=[i for i in 2.. | prime? i]
            </span>
          </li>
        </ul>
      </li>
      <li> Now we can find, for example, the 100-th prime, and the 2500-th prime:
        <ul>

```

```

    <li> <span class="cmd">primes.100</span></li>
    <li> <span class="cmd">primes.2500</span></li>
  </ul>
</li>
<li> Create random 10 digit primes:
  <ul>
    <li> <span class="cmd">p := nextPrime(random(10^10))</span></li>
    <li> <span class="cmd">q := nextPrime(random(10^10))</span></li>
  </ul>
</li>
<li> Now multiply them and factor the product.  How long did it take?</li>

<li> Try the same thing with 12 digit primes and 15 digit primes.</li>

<li> The extended Euclidean algorithm is implemented by the command
  <tt>extendedEuclidean</tt>.  Here's how to use it:
  <ul>
    <li> <span class="cmd">a:=1149</span></li>
    <li> <span class="cmd">b:=3137</span></li>
    <li> <span class="cmd">g:=extendedEuclidean(a,b)</span></li>
    <li> <span class="cmd">s:=g.coef1</span></li>
    <li> <span class="cmd">t:=g.coef2</span></li>
  </ul>
</li>
<li> and now test them:
  <ul>
    <li> <span class="cmd">s*a+t*b</span></li>
  </ul>
</li>
<li> Try this on a few other numbers.</li>

<li> Axiom uses the command <tt>positiveRemainder</tt> instead of
  <tt>mod</tt> command, so let's define <tt>mod</tt> to be a renaming
  of the <tt>positiveRemainder</tt> function:
  <ul>
    <li> <span class="cmd">mod ==> positiveRemainder</span></li>
  </ul>
</li>
<li> Now the commands <tt>addmod</tt>, <tt>submod</tt>, <tt>mulmod</tt>, and
  <tt>invmod</tt> can be used to perform modular arithmetic.  Here's a few
  examples; first a simple modulus calculation:
  <ul>
    <li> <span class="cmd">-10 mod 3</span></li>
  </ul>
</li>
<li> Addition, subtraction and multiplication mod 14:

```

```

<ul>
  <li> <span class="cmd">addmod(10,13,14)</span></li>
  <li> <span class="cmd">submod(17,23,14)</span></li>
  <li> <span class="cmd">mulmod(13,27,14)</span></li>
</ul>
</li>
<li> Powers and inverses:
  <ul>
    <li> <span class="cmd">powmod(19,237,14)</span></li>
    <li> <span class="cmd">invmod(11,14)</span></li>
  </ul>
</li>
<li> Find out what happens if you try to take an inverse of a number not
      relatively prime to the modulus:
    <ul>
      <li> <span class="cmd">invmod(12,14)</span></li>
    </ul>
</li>
<li> Try these command with a few other numbers, and test out the examples in
      the notes.
</li>
<li> The second method, which can be more powerful, is to treat all numbers
      as elements of the residue values 0 to <tt>n-1</tt>. This can be done with
      the <tt>IntegerMod</tt> construction, or its abbreviation <tt>ZMOD</tt>.
      Here's a few examples:
    <ul>
      <li> <span class="cmd">a:=11::ZMOD 14</span></li>
    </ul>
</li>
<li> This declares the variable <tt>a</tt> to be a member of the residue
      class modulo 14. Now all arithmetic including <tt>a</tt> will be
      reduced to this same class of values:
    <ul>
      <li> <span class="cmd">a+25</span></li>
      <li> <span class="cmd">a*39</span></li>
      <li> <span class="cmd">a^537</span></li>
    </ul>
</li>
<li> Inversion can be done with the <tt>recip</tt> command:
    <ul>
      <li> <span class="cmd">recip(a)</span></li>
    </ul>
</li>
<li> We don't have to define a variable first. All the above commands could
      be equivalently written as:
    <ul>

```

```

    <li> <span class="cmd">(11::ZMOD 14)+25</span></li>
    <li> <span class="cmd">11::ZMOD 14*39</span></li>
    <li> <span class="cmd">11::ZMOD 14^537</span></li>
    <li> <span class="cmd">recip(11::ZMOD 14)</span></li>
  </ul>
</li>
<li> If the modulus is a prime, then division (by non-zero values) is also
    possible. Axiom provides the alternative construction
    <tt>PrimeField</tt> or more simply <tt>PF</tt>. For example:
    <ul>
      <li> <span class="cmd">a:=7::PF 11</span></li>
    </ul>
</li>
<li> All the above arithmetic operations of addition, subtraction,
    multiplication and powers work, but now we also have inversion:
    <ul>
      <li> <span class="cmd">1/a</span></li>
    </ul>
</li>
<li> Using any of the methods you like, test out Fermat's theorem for a large
    prime <tt>p</tt> and an integer <tt>a</tt>.
</li>
<li> Euler's totient function is implemented with <tt>eulerPhi</tt>. Choose
    a large integer <tt>n</tt>, a random <tt>a</tt> with
    <tt>gcd(a,n)=1</tt> , and test Euler's theorem
</li>
</ul>
<page foot>

```

1.9.38 cryptoclass4.xhtml

```

<cryptoclass4.xhtml>≡
  <standard head>
  </head>
  <body>
  <page head>
  <center>
    <h2>RCM3720 Cryptography, Network and Computer Security</h2>
    <h3>Laboratory Class 4: Simple Cryptosystems</h3>
  </center>
  <hr/>

```

We have experimented with the Caesar cipher and the more general translation cipher. We shall start looking at the Vigenère cipher. The trick is to add the correct letter of the code to the letter of the key:

```

<pre>
  Index of plain text i: 1 2 3 4 5 6 7 8
                        Plaintext: W I T H D R A W
                        Key: C O D E C O D E
                        Index of key j: 1 2 3 4 1 2 3 4
</pre>

```

The indices of the key repeat 1, 2, 3, 4. We can get a repetition of length four by using a modulus of 4:

```

<pre>
                        i: 1 2 3 4 5 6 7 8
                        i (mod 4): 1 2 3 0 1 2 3 0
</pre>

```

What we need to do is to subtract one before the modulus, and add one after:

```

<pre>
                        i: 1 2 3 4 5 6 7 8
                        i-1: 0 1 2 3 4 5 6 7
                        i-1 (mod 4): 0 1 2 3 0 1 2 3
                        i-1 (mod 4) + 1: 1 2 3 4 1 2 3 4
</pre>

```

This means that in the Vigenère cipher, we add the i -th character of the plaintext, and the j -th character of the key, where

```

<pre>
  j=i-1 (mod n) + 1
</pre>

```

with n being the length of the key.

```

<ul>

<li> First read in the <tt>rcm3720.input</tt> file you have created:
  <ul>
    <li> <span class="cmd"><code>)read rcm3720</code></span></li>
  </ul>

  You may have to include the full path here.
</li>
<li> Enter a plaintext
  <ul>
    <li> <span class="cmd"><code>plaintext:="WITHDRAWONEHUNDREDDOLLARS"</code></span></li>
  </ul>
</li>
<li> and a keyword:
  <ul>
    <li> <span class="cmd"><code>key := "CODE"</code></span></li>
  </ul>
</li>
<li> Now we can obtain the lengths of the plaintext and key with the hash
      symbol:
  <ul>
    <li> <span class="cmd"><code>pn:=#plaintext</code></span></li>
    <li> <span class="cmd"><code>kn:=#key</code></span></li>
  </ul>
</li>
<li> Turn both plaintext and key into lists of numbers:
  <ul>
    <li> <span class="cmd"><code>pl:=str2lst(plaintext)</code></span></li>
    <li> <span class="cmd"><code>kl:=str2lst(key)</code></span></li>
  </ul>
</li>
<li> Now we can add them using the formula for <tt>j</tt> above to obtain
      the list corresponding to the ciphertext:
  <ul>
    <li>
      <span class="cmd">
        <code>cl:=[(pl.i+kl.((i-1) rem kn+1)):ZMOD 26 for i in 1..pn]
      </span>
    </li>
  </ul>
</li>
<li> And obtain the ciphertext (we need to convert our list to a list of
      integers first):
  <ul>
    <li> <span class="cmd"><code>ciphertext:=lst2str(cl::List INT)</code></span></li>
  </ul>

```

```

    </ul>
  </li>
  <li> Try a few other Vigen&#x0E8;re encryptions.</li>

  <li> To decrypt, we just <i>subtract</i> the key value from the ciphertext
  value:
  <ul>
    <li>
      <span class="cmd">
        pl:=[(cl.i+kl.((i-1) rem kn+1)):ZMOD 26 for i in 1..pn]
      </span>
    </li>
    <li> <span class="cmd">lst2str(pl::List INT)</span></li>
  </ul>
</li>
  <li> Now for the Hill (matrix) cipher. We shall use <tt>3 x 3</tt>
  matrices, so first create a plaintext whose length is a multiple of 3:
  <ul>
    <li> <span class="cmd">plaintext:="WITHDRAWONEHUNDREDDOLLARSXX"</span></li>
    <li> <span class="cmd">pl:=str2lst(plaintext)</span></li>
    <li> <span class="cmd">r:=3</span></li>
    <li> <span class="cmd">c:INT:=#pl/r</span></li>
  </ul>
</li>
  <li> The values <tt>r</tt> and <tt>c</tt> are the row and column numbers
  of the plaintext matrix.
</li>
  <li> Now put all the plaintext values into a <tt>r x c</tt> matrix:
  <ul>
    <li>
      <span class="cmd">
        S:=matrix([[pl.(r*(i-1)+j) for i in 1..c] for j in 1..r])
      </span>
    </li>
  </ul>
</li>
  <li> Create the key matrix:
  <ul>
    <li>
      <span class="cmd">
        M:Matrix ZMOD 26:=matrix([[22,11,19],[15,20,24],[25,21,16]])
      </span>
    </li>
  </ul>
</li>
  <li> Multiply the two matrices:

```

```

<ul>
  <li> <span class="cmd">C:=M*S</span></li>
</ul>
</li>
<li> Notice how the results are automatically reduced modulo 26,
      because that is how the matrix <tt>M</tt> was defined.
</li>
<li> Now we have to read off the elements of <tt>C</tt> into a single list;
      this can be done by transposing the matrix, and reading off the rows as
      lists:
      <ul>
        <li>
          <span class="cmd">
            CL:=concat(transpose(C)::List List ZMOD 26)
          </span>
        </li>
      </ul>
</li>
<li> And finally turn into ciphertext:
      <ul>
        <li> <span class="cmd">lst2str(CL::List INT)</span></li>
      </ul>
</li>
<li> Finally, here's how we can invert our matrix <tt>M</tt> modulo 26:
      <ul>
        <li> <span class="cmd">adj:=adjoint(M).adjMat</span></li>
        <li> <span class="cmd">invdet:=recip(determinant(M))</span></li>
        <li> <span class="cmd">MI:=invdet*adj</span></li>
      </ul>
</li>
<li> Or alternatively, as one command:
      <ul>
        <li>
          <span class="cmd">
            MI:=recip(determinant(M))*adjoint(M).adjMat
          </span>
        </li>
      </ul>
</li>
<li> Check the result:
      <ul>
        <li> <span class="cmd">M*MI</span></li>
      </ul>
</li>
</ul>
<page foot>

```

1.9.39 cryptoclass5.xhtml

```

<cryptoclass5.xhtml>≡
  <standard head>
  </head>
  <body>
    <page head>
    <center>
      <h2>RCM3720 Cryptography, Network and Computer Security</h2>
      <h3>Laboratory Class 5: RSA and public-key cryptosystems</h3>
    </center>
    <hr/>
    <ul>
      <li>Read in this file:
        <ul>
          <li>
            <span class="cmd">
              )read "S:/Samples/RCM3720/rcm3720.input" )quiet
            </span>
          </li>
        </ul>
      </li>
      <li>You can leave the "<tt>)quiet</tt>" off if you like. The file
        is also available <a href="rcm3720.input">here</a>.
        If you obtain it from the
        website, save it to a place of your choice, and <tt>read</tt> it
        into your Axiom session using the full path, as shown above.
      </li>
      <li>Now create some large primes and their product:
        <ul>
          <li><span class="cmd">r() == rand(2^100)</span></li>
          <li><span class="cmd">p:=nextPrime(r())</span></li>
          <li><span class="cmd">q:=nextPrime(r())</span></li>
          <li><span class="cmd">n:=p*q</span></li>
        </ul>
      </li>
      <li>Choose a value <tt>e</tt> and ensure that it is relatively prime
        to your <tt>(p-1)(q-1)</tt>, and determine
        <tt>d=e^-1 mod (p-1)(q-1)</tt>. (Use the <tt>invmod</tt> function here).
      </li>
      <li>Create a plaintext:
        <ul>
          <li><span class="cmd">pl:="This is my plaintext."</span></li>
        </ul>
      </li>
      <li>(or any plaintext you like), and convert it to a number using the

```

```

    <tt>str2num</tt> procedure from the file above:
  <ul>
    <li> <span class="cmd">pln:=str2num(pl)</span></li>
  </ul>
</li>
<li> Encrypt this number using the RSA method:
  <ul>
    <li> <span class="cmd">ct:=powmod(pln,e,n)</span></li>
  </ul>
</li>
<li> and decrypt the result:
  <ul>
    <li> <span class="cmd">decrypt:=powmod(ct,d,n)</span></li>
    <li> <span class="cmd">num2str(decrypt)</span></li>
  </ul>
</li>
<li> With a friend, swap your public keys and use them to send
      each other a ciphertext encrypted with your friend's public key.
</li>
<li> Now decrypt the ciphertext you have received using your private key.</li>

<li> Now try Rabin: create two large primes <tt>p</tt> and <tt>q</tt> and
      ensure that each is equal to 3 mod 4. (You might have to run the
      <tt>nextPrime</tt> command a few times until you get primes which work.)
</li>
<li> Create <tt>N=pq</tt> and create a plaintext <tt>pl</tt>, and its
      numerical equivalent.
</li>
<li> Determine the ciphertext <tt>c</tt> by squaring your
      number mod <tt>N</tt>.
</li>
<li> Determine the <tt>s</tt> and <tt>t</tt> for which <tt>sp+tq=1</tt>
      by using the <tt>extendedEuclidean</tt> function.
</li>
<li> Now follow through the Rabin decryption:
  <ul>
    <li> <span class="cmd">cp:=powmod(c,(p+1)/4,N) </span></li>
    <li> <span class="cmd">cq:=powmod(c,(q+1)/4,N)</span></li>
    <li>
      <span class="cmd">
        c1:=(s*p*cq+t*q*cp)::ZMOD N,num2str(c1::INT)
      </span>
    </li>
    <li>
      <span class="cmd">
        c2:=(s*p*cq-t*q*cp)::ZMOD N,num2str(c2::INT)
      </span>
    </li>
  </ul>

```

```

    </span>
  </li>
  <li>
    <span class="cmd">
      c3:=(-s*p*cq-t*q*cp)::ZMOD N,num2str(c3::INT)
    </span>
  </li>
  <li>
    <span class="cmd">
      c4:=(-s*p*cq+t*q*cp)::ZMOD N,num2str(c4::INT)
    </span>
  </li>
</ul>
</li>
<li> One of the outputs <tt>c1</tt>, <tt>c2</tt>, <tt>c3</tt> and
      <tt>c4</tt> should produce the correct plaintext; the others should be
      gibberish.
</li>
<li> As above, swap public keys with a friend, and use those public
      keys to encrypt a message to him or her. Now decrypt the ciphertext
      you have been given.
</li>
<li> For the el Gamal system, you need a large prime and a primitive
      root. Create a large prime <tt>p</tt> and find a primitive root
      <tt>a</tt> using.
    <ul>
      <li> <span class="cmd">a:=primitiveElement()$PF p</span></li>
    </ul>
</li>
<li> The <tt>primitiveElement</tt> command is not very efficient, so
      if it seems to be taking a long time, abort the computation and try
      with another prime.
</li>
<li> Do this in pairs with a friend, so that you each agree on a
      large prime and a primitive root.
</li>
<li> Now choose a random value <tt>A</tt>:
    <ul>
      <li> <span class="cmd">A:=random(p-1)</span></li>
    </ul>
</li>
<li> and create your public key <tt>A1=a^A (mod p)</tt>:
    <ul>
      <li> <span class="cmd">A1:=a^A</span></li>
    </ul>
</li>

```

```

<li> Swap public keys with your friend.</li>

<li> Create a plaintext <tt>pl</tt> and its number <tt>pln</tt>, and create
the ciphertext as follows (where <tt>A1</tt> is your friend's
public key):
<ul>
  <li> <span class="cmd">k:=random(p-1)</span></li>
  <li> <span class="cmd">K:=A1^k</span></li>
  <li> <span class="cmd">C:=[a^k, K*pln]</span></li>
</ul>
</li>
<li> This pair <tt>C</tt> is the ciphertext you send to your friend.</li>

<li> Now decrypt the ciphertext you have been sent:
<ul>
  <li> <span class="cmd">K:=C.1 ^ A</span></li>
  <li> <span class="cmd">m:=C.2/K</span></li>
  <li> <span class="cmd">num2str(m::INT)</span></li>
</ul>
</li>
</ul>
<page foot>

```

`</center>`

`<hr/>`

You will need to read in the `rcm3720.input` file for the `<tt>str2num</tt>` and `<tt>num2str</tt>` procedures.

`
`

`NOTE:` To save typing in all the messages and long signature numbers, just copy them from `signatures.txt`

``

`` For an RSA signature scheme, I provide the public key `<i>(n,e)</i>`, where

`<pre>`

`137`

`n=2137-1, e=17`

`</pre>`

``

`` This value `<tt>n</tt>` has two large prime factors.

Use my public key to verify my signature of the following message:

`<pre>`

`This is my text.`

`68767027465671577191073128495082795700768`

`</pre>`

``

`` Now try with the public key

`<pre>`

`67`

`n=(667-1)/5, e=17`

`</pre>`

``

`` to verify my signature:

`<pre>`

`Please feed my dog!`

`1703215098456351993605104919259566435843590978852633`

`</pre>`

``

 For a Rabin signature scheme, I provide the public key
<pre>

74

$N=(7^{74}-1)/6,$

</pre>

which I know can be factorized into two large primes.

 Check the following message and signature:

<pre>

Arrive Thursday.

189479723122534414019783447271411895509

</pre>

 For an El Gamal signature scheme, I choose the next prime after

<pre>

150

2

</pre>

which has a primitive root <tt>a=2</tt>. My public key is

<pre>

B=1369851585774063312693119161120024351761244461

</pre>

 Verify the signature

<pre>

Leave AT ONCE!,

1389080525305754392111976715361069425353578198

1141326468070168229982976133801721430306004477

</pre>

 For a DSS signature, choose <tt>p</tt> to be the next prime after

<pre>

170

2 and $q=143441505468590696209$

</pre>

 Verify that <tt>q</tt> is a divisor of <tt>p-1</tt>.

A primitive root of <tt>p</tt> is <tt>a=3</tt>.

Use this primitive root to determine

<pre>

$(p-1)/q$

$g = a^{(p-1)/q} \bmod p$

</pre>

```
<li> The public key value is

```

 B=1394256880659595564848116770226045673904445792389839.

```

</li>
<li> Now using these values, verify this signature:

```

 Now's your chance!
 64609209464638355801
 13824808741200493330

```

</li>
<li> Now exchange some public keys with a friend, and sign messages to each
    other. Then verify the signatures you have been sent. Make sure you try
    each of
    <ul>
        <li> RSA signatures,</li>
        <li> Rabin signatures,</li>
        <li> El Gamal signatures,</li>
        <li> DSS.</li>
    </ul>
</li>
</ul>
<page foot>

          <h3>Laboratory Class 7: Knapsack cryptosystems</h3>
        </center>
        <hr/>

```

You will need to read in the rcm3720.input file for various necessary procedures.

```
<br/><br/>
```

```
<b>The subset sum problem</b>
```

```
<br/><br/>
```

We will first experiment with this problem; creating random lists and adding up elements from them.

```

<ul>
  <li> Start with a list of eight elements:
    <ul>
      <li> <span class="cmd">ln:=8</span></li>
      <li> <span class="cmd">lst:=[random(10^6) for i in 1..ln]</span></li>
      <li> <span class="cmd">m:=[random(2) for i in 1..ln]</span></li>
      <li> <span class="cmd">c:=reduce(+,[m.i*lst.i for i in 1..ln])</span></li>
      <li> <span class="cmd">subsetsum(lst,c)</span></li>
    </ul>
  </li>
  <li> The <tt>subsetsum</tt> command implements a fairly non-efficient
    command for attempting to solve the subset sum problem for an
    arbitrary list.
  </li>
  <li> Try the above commands, but starting with a length <tt>ln</tt> of
    12. You should find the command is a bit slower this time.
    Use this command to time it:
    <ul>
      <li> <span class="cmd">)<set messages time on</span></li>
    </ul>
  </li>
  <li> Experiment with lengths of 16 and 20. How long does the
    <tt>subsetsum</tt> command take for each of these values?
  </li>

```

```

</ul>
<br/><br/>
<b>Superincreasing sequences</b>

<ul>
<li> Create a superincreasing sequence with
  <ul>
    <li> <span class="cmd">ln:=8</span></li>
    <li> <span class="cmd">lst:=[random(10^6) for i in 1..ln]</span></li>
    <li>
      <span class="cmd">
        for i in 2..ln repeat lst.i:=reduce(+,[lst.j for j in 1..i-1])+random(10)+1
      </span>
    </li>
  </ul>
</li>
<li> Now create <tt>m</tt> and <tt>c</tt> as above. This time, solve the
  problem with
  <ul>
    <li> <span class="cmd">siSolve(lst,c)</span></li>
  </ul>
</li>
<li> Now try with larger lengths: 12, 16 and 20, and time the commands each
  time.
</li>
<li> What can you say about solving the subset sum problem for general and
  superincreasing lists?
</li>
</ul>
<br/><br/>
<b>The Merkle-Hellman additive knapsack system</b>

<ul>
<li> Create a superincreasing list of length <tt>ln</tt> 10, and call it
  <tt>a</tt>. Create a new number <tt>N</tt> greater than the sum of all
  values of <tt>a</tt>. Check with
  <ul>
    <li> <span class="cmd">N>reduce(+,[a.i for i in 1..ln])</span></li>
  </ul>
</li>
<li> Now choose (randomly) a value <b>wN</b> and which is
  relatively prime to <b>N</b>. Then construct your public key:
  <ul>
    <li> <span class="cmd">b:=map(x +-> x*w rem N,a)</span></li>
  </ul>
</li>

```

```

<li> Now for an encryption and decryption. Create a random message <tt>m</tt>
as above, and encrypt it to a ciphertext <tt>c</tt> using the public key
<tt>b</tt>.
</li>
<li> Decrypt it as follows:
<ul>
  <li> <span class="cmd">c1:=inv_mod(w,N)*c rem N</span></li>
  <li> <span class="cmd">siSolve(a,c1)</span></li>
</ul>
</li>
<li>
  Experiment with longer lists and messages: 12, 16, 20 or even larger.
</li>
</ul>
<br/><br/>
<b>The Merkle-Hellman multiplicative knapsack system</b>

<ul>
<li> Choose <tt>a</tt> to be the first ten primes,
      and a large prime <tt>p</tt>:
<ul>
  <li> <span class="cmd">a:=[2,3,5,7,11,13,17,19,23,29]</span></li>
  <li> <span class="cmd">p:=6469785001</span></li>
</ul>
</li>
<li> Check that <tt>p</tt> is greater than the product of all elements of
      <tt>a</tt>:
<ul>
  <li> <span class="cmd">p>reduce(*,[a.i for i in 1..10])</span></li>
</ul>
</li>
<li> and that <tt>p-1</tt> has only small factors:
<ul>
  <li> <span class="cmd">factor(p-1)</span></li>
</ul>
</li>
<li> Choose as a primitive root the value 34:
<ul>
  <li> <span class="cmd">r:=34</span></li>
  <li> <span class="cmd">primitive?(r)$PF(p)</span></li>
</ul>
</li>
<li> and compute the public key:
<ul>
  <li> <span class="cmd">b:=map(x --> discreteLog(r,x)$PF(p),a)</span></li>
</ul>

```

```
</li>
<li> Create a message of length 10, and encrypt it using the public key
  <tt>b</tt>:
  <ul>
    <li>
      <span class="cmd">
        c:=reduce(+,[m.i*b.i::INT for i in 1..ln])
      </span>
    </li>
  </ul>
</li>
<li> Decryption is now done with:
  <ul>
    <li> <span class="cmd">c1:=powmod(r,c,p)</span></li>
    <li> <span class="cmd">factor(c1)</span></li>
  </ul>
</li>
</ul>
<page foot>
```

1.9.42 cryptoclass8.xhtml

```

<cryptoclass8.xhtml>≡
  <standard head>
    </head>
    <body>
      <page head>
        <center>
          <h2>RCM3720 Cryptography, Network and Computer Security</h2>
          <h3>Laboratory Class 8: Modes of Encryption</h3>
        </center>
        <hr/>

```

We will investigate the different modes of encryption using the Hill (matrix) cryptosystem. Start off by entering some matrices:

```

<ul>
  <li>
    <span class="cmd">
      M:=matrix([[15,9,21],[2,10,7],[16,11,12]]):Matrix ZMOD 26
    </span>
  </li>
  <li>
    <span class="cmd">
      MI:=matrix([[7,17,19],[24,0,23],[12,25,10]]):Matrix ZMOD 26
    </span>
  </li>
</ul>

```

Check that you've entered everything correctly with

```

<ul>
  <li> <span class="cmd">M*MI</span></li>
</ul>

```

Note that because the matrices were defined in terms of numbers mod 26, their product is automatically reduced mod 26.

Now enter the following column vector:

```

<ul>
  <li>
    <span class="cmd">
      zero31:=matrix([[0],[0],[0]]):Matrix ZMOD 26
    </span>
  </li>
</ul>

```

For this lab, rather than fiddling about with translations between

letters and numbers, all our work will be done with numbers alone
(in the range 0..25).

```
<br/><br/>
<b>ECB</b>
<br/><br/>
```

For electronic codebook mode, encryption is performed by multiplying each plaintext block by the matrix, and decryption by multiplying each ciphertext block by the inverse matrix:

```
<pre>
                -1
      C =M.P ,  P =M  C
        i      i      i      i
</pre>
```

where all arithmetic is performed mod 26.

```
<ul>
<li> Start by entering a plaintext, which will be a list of column vectors:
  <ul>
    <li>
      <span class="cmd">
        P:=[matrix([[3*i],[3*i+1],[3*i+2]]) for i in 0..7]
      </span>
    </li>
  </ul>
</li>
<li> and a list which will receive the ciphertext:
  <ul>
    <li> <span class="cmd">C:=[zero31 for i in 1..8]</span></li>
  </ul>
</li>
<li> and encrypt it:
  <ul>
    <li> <span class="cmd">for i in 1..8 repeat C.i:=M*P.i</span></li>
  </ul>
</li>
<li> Now decrypt (first make an empty list <tt>D</tt>):
  <ul>
    <li> <span class="cmd">D:=[zero31 for i in 1..8]</span></li>
    <li> <span class="cmd">for i in 1..8 repeat D.i:=MI*C.i</span></li>
  </ul>
</li>
<li> If all has worked out, the list <tt>D</tt> should be the same
      plaintext you obtained earlier.
</li>
<li> Now change one value in the plaintext:
```

```

<ul>
  <li> <span class="cmd">Q:=P</span></li>
  <li> <span class="cmd">Q.3:=matrix([[6],[19],[8]])</span></li>
</ul>
</li>
<li> Now encrypt the new plaintext <tt>Q</tt> to a ciphertext <tt>E</tt>. How
does this ciphertext differ from the ciphertext <tt>C</tt> obtained from
<tt>P</tt>?
</li>
<li> Check that you can decrypt <tt>E</tt> to obtain <tt>Q</tt>.</li>
</ul>
<br/><br/>
<b>CBC</b>
<br/><br/>
For cipherblock chaining mode, the encryption formula for the Hill
cryptosystem is
<pre>
  C =M(P +C  )
    i   i   i-1
</pre>
and decryption is
<pre>
  -1
  P =M  C -C
    i   i   i-1
</pre>

<ul>
<li> To enable us to use these formulas, we shall first add an extra column
to the front of <tt>P</tt> and <tt>C</tt>:
  <ul>
    <li> <span class="cmd">P:=append([zero31],P)</span></li>
    <li> <span class="cmd">C:=append([zero31],C)</span></li>
  </ul>
</li>
<li> And we need to create a initialization vector:
  <ul>
    <li> <span class="cmd">IV:=matrix([[random(26)] for i in 1..3])</span></li>
  </ul>
</li>
<li> Now for encryption:
  <ul>
    <li> <span class="cmd">C.1:=IV</span></li>
    <li>
      <span class="cmd">
        for i in 2..9 repeat C.i:=M*(P.i+C.(i-1))
      </span>
    </li>
  </ul>

```

```

    </span>
  </li>
</ul>
</li>
<li> Let's try to decrypt the ciphertext, using the CBC formula:
  <ul>
    <li> <span class="cmd">D:=[zero31 for i in 1..9]</span></li>
    <li>
      <span class="cmd">
        for i in 2..9 repeat D.i:=MI*(C.i)-C.(i-1)
      </span>
    </li>
  </ul>
</li>
<li> Did it work out?</li>

<li> As before, change one value in the plaintext:
  <ul>
    <li> <span class="cmd">Q:=P</span></li>
    <li> <span class="cmd">Q.4:=matrix([[6],[19],[8]])</span></li>
  </ul>
</li>
<li> Now encrypt <tt>Q</tt> to <tt>E</tt> following the procedure outlined
      above. Compare <tt>E</tt> with <tt>C</tt>---
      how much difference is there?
      How does this difference compare with the differences of ciphertexts
      obtained with ECB?
</li>
<li> Just to make sure you can do it, decrypt <tt>E</tt> and make sure you
      end up with a list equal to <tt>Q</tt>.
</li>
</ul>
<br/><br/>
<b>OFB</b>
<br/><br/>
Output feedback mode works by creating a <i>key stream</i>, and then adding
it to the plaintext to obtain the ciphertext. With the Hill system, and an
initialization vector <tt>IV</tt>:
<pre>
  k =IV,    k =Mk
    1      i   i-1
</pre>
and then
<pre>
  c =p +k
    i   i   i

```

```
</pre>
```

```
<ul>
```

```
<li> First, the key stream:
```

```
<ul>
```

```
<li> <span class="cmd">K:=[zero31 for i in 1..9]</span></li>
```

```
<li> <span class="cmd">K.1:=IV</span></li>
```

```
<li> <span class="cmd">for i in 2..9 repeat K.i:=M*K.(i-1)</span></li>
```

```
</ul>
```

```
</li>
```

```
<li> and next the encryption:
```

```
<ul>
```

```
<li> <span class="cmd">for i in 2..9 repeat C.i:=K.i+P.i</span></li>
```

```
</ul>
```

```
</li>
```

```
<li> What is the formula for decryption?
```

```
    Apply it to your ciphertext <tt>C</tt>.
```

```
</li>
```

```
</ul>
```

```
<page foot>
```

1.9.43 cryptoclass9.xhtml

```

<cryptoclass9.xhtml>≡
  <standard head>
  </head>
  <body>
  <page head>
  <center>
    <h2>RCM3720 Cryptography, Network and Computer Security</h2>
    <h3>Laboratory Class 9: Hash Functions</h3>
  </center>
  <hr/>
  <br/><br/>
  <b>A simple hash</b>
  <br/><br/>
  Given two prime numbers <tt>p</tt> and <tt>q</tt>, and their product
  <tt>N</tt>, we can define a hash of a number <tt>n</tt> to be
  <pre>
      n
      hash = g  (mod N)
  </pre>

```

This is provably collision resistant, because if we want to find two hashes which are equal, then we need to find <tt>m</tt> and <tt>n</tt> for which

```

  <pre>
      m    n
      g  = g  (mod N)
  </pre>
  or that
  <pre>
      m-n
      g  = 1 (mod N)
  </pre>

```

By Euler's theorem, we know that

```

  <pre>
      &#x3D5;(N)
      g      = 1 (mod N)
  </pre>

```

This means that finding a collision requires finding two numbers <tt>m</tt> and <tt>n</tt> for which

```

  <pre>
      m = n (mod &#x3D5;(N))
  </pre>

```

Since computing $\phi(N)$ requires a knowledge of the factorization of N , this will be hard if p and q are large.

```
<ul>
  <li> Enter the following commands:
    <ul>
      <li> <span class="cmd">p:=nextPrime(87654321)</span></li>
      <li> <span class="cmd">q:=nextPrime(98765432)</span></li>
      <li> <span class="cmd">N:=p*q</span></li>
      <li> <span class="cmd">g:=17</span></li>
    </ul>
  </li>
  <li> Read in the utility file <a href="rcm3720.input">rcm3720.input</a></li>

  <li> Now experiment with the following hashes:
    <ul>
      <li> <span class="cmd">n:=str2num("A cat")</span></li>
      <li> <span class="cmd">h:=powmod(g,n,N)</span></li>
      <li> <span class="cmd">n:=str2num("A bat")</span></li>
      <li> <span class="cmd">h:=powmod(g,n,N)</span></li>
    </ul>
  </li>

  <li> Even though the strings are very similar,
        how similar are the hash values?
  </li>
  <li> Experiment with hashing some other strings---some short, some long.</li>

  <li> Read in a text file (any text file, of any length) as follows:</li>
    <ul>
      <li>
        <span class="cmd">
          f:TextFile:=open("\full\path\to\file","input")
        </span>
      </li>
      <li> <span class="cmd">str:=""</span></li>
      <li>
        <span class="cmd">
          while not endOfFile?(f) repeat str:=concat(str,readLine(f));
        </span>
      </li>
    </ul>

  <li> Now the variable <tt>str</tt> will contain the file as one long string.
        Hash this string, by converting it to a number first.
  </li>
```

```

<li> Try this with a few different text files,
      of different lengths---some short, some long.
</li>
</ul>

```

```

<br/><br/>

```

```

<b>A simplified version of MASH</b>

```

```

<br/><br/>

```

We shall experiment with a simplified version of the MASH hash function:

```

<ol>
  <li> Start with two prime numbers <tt>p</tt> and <tt>q</tt>,
      and their product <tt>N</tt>.
  </li>
  <li> Turn the data to be hashed into a single integer <tt>n</tt>.</li>

```

```

  <li> Express <tt>n</tt> as ‘‘digits’’ in base <tt>N</tt>:</li>

```

```

<pre>

```

$$n = a_0 + a_1 N + a_2 N^2 + a_3 N^3 + \dots + a_q N^q$$

```

</pre>

```

```

  <li> Start with <tt>H</tt> being the largest prime less than <tt>N</tt>.</li>

```

```

  <li> For <tt>i</tt> from 0 to <tt>q</tt></li>

```

```

<pre>

```

$$H \leftarrow (H + a_i)^2 \pmod{N}$$

```

</pre>

```

```

  <li> The final value of <tt>H</tt> is the hash.</li>

```

```

</ol>

```

```

<ul>

```

```

  <li> With <tt>p</tt>, <tt>q</tt> and <tt>N</tt> as before, pick a long
      string (or the string from a text file) to be hashed, and turn it
      into a number <tt>n</tt>.

```

```

  </li>

```

```

  <li> Determine the ‘‘digits’’ in base <tt>N</tt>:

```

```

    <ul>

```

```

      <li>

```

```

        <span class="cmd">

```

```

          a:=wholeRagits(n::RadixExpansion(N))::List ZMOD N

```

```

        </span>

```

```

      </li>
    </ul>

```

```
</ul>
</li>
<li> Now create the hash:
  <ul>
    <li> <span class="cmd">H:=prevPrime(N)</span></li>
    <li> <span class="cmd">for i in 1..#a repeat H:=(H+a.i)^2+H</span></li>
  </ul>
</li>
<li> Note that since the elements of the list <tt>a</tt> are already
      defined as being modulo <tt>N</tt>, we don't have to use a mod
      function in this last step.
</li>
<li> Create the hashes of a few other strings and files.  What happens if you
      try to hash a really long text file?
</li>
<li> Experiment with hashing using some other (large) primes.</li>
</ul>
<page foot>
```

1.9.44 cryptoclass10.xhtml

```

<cryptoclass10.xhtml>≡
  <standard head>

  <center>
    <h2>RCM3720 Cryptography, Network and Computer Security</h2>
    <h3>Laboratory Class 10: The Data Encryption Standard</h3>
  </center>
  <hr/>

```

The object of this lab will be to build up the necessary functions and tools to implement simplified DES (sDES). All operations will be done on binary lists. Since the definitions of the sDES functions require lists to be indexed starting at 0, but in Axiom lists are indexed starting at 1, many of the operations will have extra ones added at some stage.

- ```

 Save the file <tt>des.input</tt> to a directory in which you
 have write access. Read the file into Axiom, and open up the file
 with a text editor.

 Compare the first command <tt>perm(b)</tt> with the initial
 permutation for sDES defined in page 94 of the notes. How do the
 indices in the Axiom command relate to the indices of the
 permutation in the notes?

 Now using the above procedure as a guide, write a procedure called
 <tt>invperm</tt> to perform the inverse permutation.

 Test this procedure: it should invert the permutation you
 obtained from the <tt>perm</tt> procedure.

 The <tt>subkey</tt> procedure creates two lists: one for the
 first subkey, and one for the second. Edit the procedure to include
 the second subkey as given on the bottom of page 95.

 Write a procedure called <tt>expperm</tt> which implements the
 expansion permutation on page 96; use the <tt>perm</tt> and

```

- <tt>invperm</tt> procedures as guides.
- </li>
- <li> Using the <tt>sbox0</tt> procedure as a guide, write a procedure to implement S-box 1.
- </li>
- <li> The mixing function shown in figure 8.5 in the notes is implemented as <tt>mix</tt>. This procedure has been commented.
- </li>
- <li> Comment each line of the <tt>feistel</tt> and <tt>sdes</tt> procedures in a similar fashion.
- </li>
- <li> Test the <tt>sdes</tt> procedure on the example given in the notes.
- </li>
- <li> Modify your procedure to implement sDES decryption, using the scheme given on page 99.
- </li>
- <li> Test that your decryption procedure works; that it decrypts the ciphertext produced by your encryption procedure to the original plaintext.
- </li>

</ul>

## 1.9.45 cryptoclass11.xhtml

```

<cryptoclass11.xhtml>≡
 <standard head>
 </head>
 <body>
 <page head>
 <center>
 <h2>RCM3720 Cryptography, Network and Computer Security</h2>
 <h3>Laboratory Class 11: Finite Fields</h3>
 </center>
 <hr/>

 Enter the following definition of the finite field
 <pre>
 3
 Z [x]/(x +x+1)
 2
 </pre>

 F:=FFP(PF 2,x^3+x+1)

 To perform field operations, we need to create a generator of the field:
 a symbol which can be used to generate all elements as polynomials:

 x:=generator()$F

 Now field arithmetic is easy:

 (x^2+1)(x+1) in the field:

 (x^2+1)*(x+1)

 1/(x^2+x):

 1/(x^2+x)

Note that Axiom returns its answer in terms of a dummy variable.

 We can also list tables of powers:

```

```

 for i in 0..7 repeat output (i::String, x^i)

 Before we enter a new field, we need to clear <tt>x</tt> and its
properties:

 <code>cl pr x</code>

 Now for a slightly bigger field:
<pre>
 4 3
 Z [x]/(x +x +1)
 2
</pre>

 <code>F2:=FFP(PF 2,x^4+x^3+1)</code>

 Create a list of powers of <tt>x</tt>.
 Evaluate $(x^3+x+1)/(x^3+x^2)$ in this field.

 Enter the Rijndael field,
<pre>
 8 4 3
 Z [x]/(x +x +x +x+1)
 2
</pre>
 and call it <tt>GR</tt>.

 Determine whether <tt>x</tt> is a primitive element in this field:

 <code>x:=generator()$GR</code>
 <code>primitive?(x)</code>

 Is <tt>x+1</tt> a primitive element?

 Investigate the workings of MixColumn. First create the matrix:

```

```

M:Matrix GR:=matrix([[x,x+1,1,1],[1,x,x+1,1],[1,1,x,x+1],[x+1,1,1,x]])

```

Instead of multiplying a matrix  $C$  by  $M$ , we shall just look at a single column, created randomly:

```

C:Matrix GR:=matrix([[random()$FR] for j in 1..4])

```

These can be multiplied directly in Axiom:

```

 D:=M*C

```

Remarkably enough, Axiom can operate on matrices over a finite field as easily as it can operate on numerical matrices. For example, given that

```

<pre>
D=MC
</pre>
 it follows that
<pre>
-1
C=M D
</pre>
 or that
<pre>
-1
M D-C=0
</pre>
 To test this, first create the matrix inverse:
 MI:=inverse(M)

```

```

 Now multiply by <tt>D</tt> and subtract <tt>C</tt>. What does the result
 tell you about the truth of the final equation?

 To explore MixColumn a bit more, we shall look at the inverse of
 <tt>M</tt>. First, here's a small function which converts from
 a polynomial to an integer (treating the coefficients of the
 polynomial as digits of a binary number):

 poly2int(p)==(tmp:=reverse(coordinates(p)),return
 integer wholeRadix(tmp::LIST INT)$RadixExpansion(2))

 First check the matrix <tt>M</tt>:

 map((x +-> poly2int(x)::INT), M)

 Is this what you should have?

 Now apply the same command but to <tt>MI</tt> instead of to <tt>M</tt>.
 What is the result?

 function cmdline(arg) {
 var myform = document.getElementById("form2");
 var ans='integrate('+myform.expr.value+', '+myform.vars.value+'='+
 myform.lower.value+'..'+myform.upper.value+')';
 return(ans);
 }
 </script>
 </head>
 <body>
 <page head>
 <form id="form2">
 Enter the function you want to integrate:

 <input type="text" id="expr" tabindex="10" size="50"
 value="1/(x^2+6)"/>

 Enter the variable of integration:

 <input type="text" id="vars" tabindex="20" size="5" value="x"/>

 Enter a lower limit:

 <input type="text" id="lower" tabindex="30" value="%minusInfinity"/>

 Enter an upper limit:

 <input type="text" id="upper" tabindex="40" value="%plusInfinity"/>

 </form>
 <continue button>
 <answer field>
 <page foot>

```

### 1.9.290 determinantofhilbert.xhtml

```

<determinantofhilbert.xhtml>≡
 <standard head>
 <script type="text/javascript">
 <handlefreevars>
 <axiom talker>
 </script>
 </head>
 <body>
 <page head>
 <div align="center">Example: Determinant of a Hilbert Matrix</div>
 <hr/>

```

Consider the problem of computing the determinant of a 10 by 10 Hilbert matrix. The  $(i,j)$ -th entry of a Hilbert matrix is given by  $1/(i+j+1)$ .

First do the computation using rational numbers to obtain the exact result.

```

 <input type="submit" id="p1" class="subbut"
 onclick="makeRequest('p1');"
 value="a:Matrix FRAC INT:=matrix [[1/(i+j+1) for j in 0..9] for i in 0..9]"
 />
 <div id="ansp1"><div></div></div>

```

This version of [determinant](dbopdeterminant.xhtml) uses Gaussian elimination.

```

 <input type="submit" id="p2" class="subbut"
 onclick="makeRequest('p2');"
 value="d:=determinant a" />
 <div id="ansp2"><div></div></div>

 <input type="submit" id="p3" class="subbut"
 onclick="handleFree(['p2','p3']);"
 value="d::Float" />
 <div id="ansp3"><div></div></div>

```

Now use hardware floats.

```

```

```

<div></div></div>

```

The result given by hardware floats is correct to only four significant digits of precision. In the jargon of numerical analysis, the Hilbert matrix is said to be "ill-conditioned".

```

<div></div></div>

```

Now repeat the computation at a higher precision using

```

Float

<div></div></div>

<div></div></div>

<div></div></div>

Reset digits to its default value.

```

```

 <input type="submit" id="p9" class="subbut"
 onclick="makeRequest('p9');"
 value="digits 20" />
 <div id="ansp9"><div></div></div>

<page foot>

```

 Approximations in the Complex Plane

 <h4>Rational Approximations</h4>

 <p>

 Cody and Hillstrom(1967)
 gives minimax rational approximations for
 <m:math display="inline">
 <m:mrow>
 <m:mi>ln</m:mi>
 <m:mrow>
 <m:mi mathvariant="normal">Γ</m:mi>
 <m:mrow>
 <m:mo>(</m:mo>
 <m:mi>x</m:mi>
 <m:mo>)</m:mo>
 </m:mrow>
 </m:mrow>
 </m:mrow>
 </m:math> for the ranges
 <m:math display="inline">
 <m:mrow>
 <m:mn>0.5</m:mn>
 <m:mo>≤</m:mo>
 <m:mi>x</m:mi>
 </m:mrow>
 </m:math>

```

```

 <m:mo>≤</m:mo>
 <m:mn>1.5</m:mn>
 </m:mrow>
</m:math>,

<m:math display="inline">
 <m:mrow>
 <m:mn>1.5</m:mn>
 <m:mo>≤</m:mo>
 <m:mi>x</m:mi>
 <m:mo>≤</m:mo>
 <m:mn>4</m:mn>
 </m:mrow>
</m:math>,
<m:math display="inline">
 <m:mrow>
 <m:mn>4</m:mn>
 <m:mo>≤</m:mo>
 <m:mi>x</m:mi>
 <m:mo>≤</m:mo>
 <m:mn>12</m:mn>
 </m:mrow>
</m:math>; precision is variable.

 Hart et.al.(1968)
 gives minimax polynomial and rational approximations to

<m:math display="inline">
 <m:mrow>
 <m:mi mathvariant="normal">Γ</m:mi>
 <m:mrow>
 <m:mo>(</m:mo>
 <m:mi>x</m:mi>
 <m:mo>)</m:mo>
 </m:mrow>
 </m:mrow>
</m:math> and
<m:math display="inline">
 <m:mrow>
 <m:mi>ln</m:mi>
 <m:mrow>
 <m:mi mathvariant="normal">Γ</m:mi>
 <m:mrow>
 <m:mo>(</m:mo>
 <m:mi>x</m:mi>
 <m:mo>)</m:mo>

```

```

 </m:mrow>
 </m:mrow>
</m:mrow>
</m:math> in the intervals

<m:math display="inline">
 <m:mrow>
 <m:mn>0</m:mn>
 <m:mo>≤</m:mo>
 <m:mi>x</m:mi>
 <m:mo>≤</m:mo>
 <m:mn>1</m:mn>
 </m:mrow>
</m:math>,

<m:math display="inline">
 <m:mrow>
 <m:mn>8</m:mn>
 <m:mo>≤</m:mo>
 <m:mi>x</m:mi>
 <m:mo>≤</m:mo>
 <m:mn>1000</m:mn>
 </m:mrow>
</m:math>,

<m:math display="inline">
 <m:mrow>
 <m:mn>12</m:mn>
 <m:mo>≤</m:mo>
 <m:mi>x</m:mi>
 <m:mo>≤</m:mo>
 <m:mn>1000</m:mn>
 </m:mrow>
</m:math>; precision is variable.

 Cody et.al.(1973)
 gives minimax rational approximations for
<m:math display="inline">
 <m:mrow>
 <m:mi>ψ</m:mi>
 <m:mrow>
 <m:mo>(</m:mo>
 <m:mi>x</m:mi>
 <m:mo>)</m:mo>
 </m:mrow>
 </m:mrow>

```

```

 </m:mrow>
 </m:math> for the ranges

 <m:math display="inline">
 <m:mrow>
 <m:mn>0.5</m:mn>
 <m:mo>≤</m:mo>
 <m:mi>x</m:mi>
 <m:mo>≤</m:mo>
 <m:mn>3</m:mn>
 </m:mrow>
 </m:math> and

 <m:math display="inline">
 <m:mrow>
 <m:mn>3</m:mn>
 <m:mo>≤</m:mo>
 <m:mi>x</m:mi>
 <m:mo><</m:mo>
 <m:mi mathvariant="normal">∞</m:mi>
 </m:mrow>
 </m:math>; precision is variable.
</p>

<p>For additional approximations see

 Hart et.al.(1968)
(Appendix B),

 Luke(1975)
(pp. 2223), and

 Weniger(2003)
.
</p>

<h4>Expansions in Chebyshev Series</h4>

<p>

 Luke(1969)

gives the coefficients to 20D for the Chebyshev-series expansions of
<m:math display="inline">
 <m:mrow>
 <m:mi mathvariant="normal">Γ</m:mi>

```

```

<m:mrow>
 <m:mo>(</m:mo>
 <m:mrow>
 <m:mn>1</m:mn>
 <m:mo>+</m:mo>
 <m:mi>x</m:mi>
 </m:mrow>
 <m:mo>)</m:mo>
 </m:mrow>
</m:mrow>
</m:math>,
<m:math display="inline">
 <m:mfrac bevelled="true">
 <m:mn>1</m:mn>
 <m:mrow>
 <m:mi mathvariant="normal">Γ</m:mi>
 <m:mrow>
 <m:mo>(</m:mo>
 <m:mrow>
 <m:mn>1</m:mn>
 <m:mo>+</m:mo>
 <m:mi>x</m:mi>
 </m:mrow>
 <m:mo>)</m:mo>
 </m:mrow>
 </m:mrow>
 </m:mfrac>
 </m:math>,

<m:math display="inline">
 <m:mrow>
 <m:mi mathvariant="normal">Γ</m:mi>
 <m:mrow>
 <m:mo>(</m:mo>
 <m:mrow>
 <m:mi>x</m:mi>
 <m:mo>+</m:mo>
 <m:mn>3</m:mn>
 </m:mrow>
 <m:mo>)</m:mo>
 </m:mrow>
 </m:mrow>
 </m:math>,

<m:math display="inline">
 <m:mrow>

```

```

<m:mi>ln</m:mi>
<m:mrow>
 <m:mi mathvariant="normal">Γ</m:mi>
 <m:mrow>
 <m:mo>(</m:mo>
 <m:mrow>
 <m:mi>x</m:mi>

 <m:mn>3</m:mn>
 </m:mrow>
 <m:mo>)</m:mo>
 </m:mrow>
</m:mrow>
</m:math>,

```

```

<m:math display="inline">
 <m:mrow>
 <m:mi>ψ</m:mi>
 <m:mrow>
 <m:mo>(</m:mo>
 <m:mrow>
 <m:mi>x</m:mi>
 <m:mo>+</m:mo>
 <m:mn>3</m:mn>
 </m:mrow>
 <m:mo>)</m:mo>
 </m:mrow>
 </m:mrow>
</m:math>, and the first six derivatives of

```

```

<m:math display="inline">
 <m:mrow>
 <m:mi>ψ</m:mi>
 <m:mrow>
 <m:mo>(</m:mo>
 <m:mrow>
 <m:mi>x</m:mi>
 <m:mo>+</m:mo>
 <m:mn>3</m:mn>
 </m:mrow>
 <m:mo>)</m:mo>
 </m:mrow>
 </m:mrow>
 </m:math> for

```

```

<m:math display="inline">
 <m:mrow>
 <m:mn>0</m:mn>
 <m:mo>≤</m:mo>
 <m:mi>x</m:mi>
 <m:mo>≤</m:mo>
 <m:mn>1</m:mn>
 </m:mrow>
</m:math>. These coefficients are reproduced in

 Luke(1975)
.

 Clenshaw(1962)
 also gives 20D Chebyshev-series coefficients for
<m:math display="inline">
 <m:mrow>
 <m:mi mathvariant="normal">Γ</m:mi>
 <m:mrow>
 <m:mo>(</m:mo>
 <m:mrow>
 <m:mn>1</m:mn>
 <m:mo>+</m:mo>
 <m:mi>x</m:mi>
 </m:mrow>
 <m:mo></m:mo>
 </m:mrow>
 </m:mrow>
 </m:math> and its reciprocal for

<m:math display="inline">
 <m:mrow>
 <m:mn>0</m:mn>
 <m:mo>≤</m:mo>
 <m:mi>x</m:mi>
 <m:mo>≤</m:mo>
 <m:mn>1</m:mn>
 </m:mrow>
</m:math>. See

 Luke(1975)
(pp.2223) for additional expansions.
</p>

<h4>Approximations in the Complex Plane</h4>

```

 Digital Library of Mathematical Functions

 The Gamma Function -- Graphics
 </div>
 <hr/>
 <h3>Graphics</h3>
 <h6>Contents</h6>

 Real Argument
 The Psi Function
 Complex Argument

 <h4>Real Argument</h4>

 This graph shows the
 <m:math display="inline">
 <m:mrow>
 <m:mi mathvariant="normal">Γ</m:mi>
 <m:mrow>
 <m:mo>(</m:mo>
 <m:mi>x</m:mi>
 <m:mo>)</m:mo>
 </m:mrow>
 </m:mrow>
 </m:math> and
 <m:math display="inline">
 <m:mfrac bevelled="true">
 <m:mn>1</m:mn>
 <m:mrow>
 <m:mi mathvariant="normal">Γ</m:mi>
 <m:mrow>
 <m:mo>(</m:mo>
 <m:mi>x</m:mi>
 <m:mo>)</m:mo>
 </m:mrow>
 </m:mrow>
 </m:mrow>
 </m:math>

```

```

</m:mfrac>
</m:math>.

```

To create these two graphs in Axiom:

```

<pre>
-- Draw the first graph in a viewport
viewport1:=draw(Gamma(i), i=-4.2..4, adaptive==true, unit==[1.0,1.0])
-- Draw the second graph in a viewport
viewport2:=draw(1/Gamma(i), i=-4.2..4, adaptive==true, unit==[1.0,1.0])
-- Get the Gamma graph from the first viewport and layer it on top
putGraph(viewport2,getGraph(viewport1,1),2)
-- Remove the points and leave the lines
points(viewport2,1,"off")
points(viewport2,2,"off")
-- Show the combined graph
makeViewport2D(viewport2)
</pre>

```

```

```

```

<m:math display="inline">

```

```

<m:mrow>

```

```

<m:mi>ln</m:mi>

```

```

<m:mrow>

```

```

<m:mi mathvariant="normal">Γ</m:mi>

```

```

<m:mrow>

```

```

<m:mo>(</m:mo>

```

```

<m:mi>x</m:mi>

```

```

<m:mo>)</m:mo>

```

```

</m:mrow>

```

```

</m:mrow>

```

```

</m:math>. This function is convex on

```

```

<m:math display="inline">

```

```

<m:mrow>

```

```

<m:mo>(</m:mo>

```

```

<m:mrow>

```

```

<m:mn>0</m:mn>

```

```

<m:mo>,</m:mo>

```

```

<m:mi mathvariant="normal">∞</m:mi>

```

```

</m:mrow>

```

```

<m:mo>)</m:mo>

```

```

</m:mrow>

```

```

</m:math>;

```

```

```

```

compare

```

## Functional Relations

&lt;p&gt;

You can construct this graph with the Axiom commands:

&lt;pre&gt;

```
-- draw the graph of log(Gamma) in a viewport
viewport1:=draw(log Gamma(i), i=0..8, adaptive==true, unit==[1.0,1.0])
-- turn off the points and leave the lines
points(viewport1,1,"off")
```

&lt;/pre&gt;

&lt;/p&gt;

&lt;br/&gt;

## &lt;h4&gt;The Psi Function

&lt;m:math display="inline"&gt;

&lt;m:mrow&gt;

&lt;m:mi&gt;&amp;#x03C8;&lt;/m:mi&gt;

&lt;m:mrow&gt;

&lt;m:mo&gt;&lt;/m:mo&gt;

&lt;m:mi&gt;x&lt;/m:mi&gt;

&lt;m:mo&gt;&lt;/m:mo&gt;

&lt;/m:mrow&gt;

&lt;/m:mrow&gt;

&lt;/m:math&gt;

&lt;/h4&gt;

<p> This function is a special case of the polygamma function.  
In particular,

&lt;m:math display="inline"&gt;

&lt;m:mrow&gt;

&lt;m:mi&gt;&amp;#x03C8;&lt;/m:mi&gt;

&lt;m:mrow&gt;

&lt;m:mo&gt;&lt;/m:mo&gt;

&lt;m:mi&gt;x&lt;/m:mi&gt;

&lt;m:mo&gt;&lt;/m:mo&gt;

&lt;/m:mrow&gt;

&lt;/m:mrow&gt;

&lt;/m:math&gt; is equal to polygamma(0,x).

&lt;/p&gt;

&lt;br/&gt;

&lt;br/&gt;

&lt;img width="522" height="556" alt="" src="bitmaps/psi.png"/&gt;

&lt;br/&gt;

You can reconstruct this graph in Axiom by:

&lt;pre&gt;

```
-- first construct the psi function
```

```

psi(x)==polygamma(0,x)
-- draw the graph in a viewport
viewport:=draw(psi(y),y=-3.5..4,adaptive==true)
-- make the gradient obvious
scale(viewport,1,0.9,22.5)
-- and recenter the graph
translate(viewport,1,0,-0.02)
-- turn off the points and keep the line
points(viewport,1,"off")
</pre>

```

<h4>Complex Argument</h4>

```

<m:math display="inline">
 <m:mrow>
 <m:mrow>
 <m:mi mathvariant="normal">Γ</m:mi>
 <m:mrow>
 <m:mo>(</m:mo>
 <m:mrow>
 <m:mi>x</m:mi>
 <m:mo>+</m:mo>
 <m:mrow>
 <m:mi mathvariant="normal">ⅈ</m:mi>
 <m:mi>y</m:mi>
 </m:mrow>
 </m:mrow>
 <m:mo></m:mo>
 </m:mrow>
 </m:mrow>
 </m:math>.

```

You can reconstruct this image in Axiom with:

```

<pre>
-- Set up the default viewpoint
viewPhiDefault(-%pi/4)
-- define the point set function
gam(x,y)==
 g:=Gamma complex(x,y)
 point [x,y,max(min(real g,4),-4), argument g]
-- draw the image and remember the viewport
viewport:=draw(gam, -4..4,-3..3,var1Steps==100,var2Steps==100)

```

```

-- set the color mapping for the image
colorDef(viewport,blue(),blue())
-- and smoothly shade it
drawStyle(viewport,"smooth")
</pre>

<m:math display="inline">
 <m:mfrac bevelled="true">
 <m:mn>1</m:mn>
 <m:mrow>
 <m:mrow>
 <m:mi mathvariant="normal">⋅</m:mi>
 </m:mrow>
 <m:mo>(</m:mo>
 <m:mrow>
 <m:mi>x</m:mi>
 <m:mo>+</m:mo>
 </m:mrow>
 <m:mi mathvariant="normal">⋅</m:mi>
 <m:mi>y</m:mi>
 </m:mrow>
 </m:mrow>
</m:mfrac>
</m:math>

<p>
You can reproduce this image from Axiom with:
<pre>
-- Set up the default viewpoint
viewPhiDefault(-%pi/4)
-- Define the complex Gamma inverse function
gaminv(x,y)==
 g:=1/(Gamma complex(x,y))
 point [x,y,max(min(real g,4),-4), argument g]
-- draw the 3D image and remember the viewport
viewport:=draw(gaminv, -4..4,-3..3,var1Steps==100,var2Steps==100)
-- make the image a uniform color
colorDef(viewport,blue(),blue())
-- and make it pretty
drawStyle(viewport,"smooth")

```

```
</pre>
</p>
```

```
<p>
```

To get these exact images with the colored background you need to use GIMP to set the background. The steps I used are:

```

```

```
Save the image as a pixmap
```

```
Open the saved file in gimp
```

```
Dialogs->Colors->ColorPicker button
```

```
Eyedrop the color of the web page
```

```
Set the color as the foreground on the FG/BG page
```

```
Dialogs->Layers
```

```
Duplicate Layer
```

```
Layer->Stack->Select bottom layer
```

```
Edit->Fill with Foreground color
```

```
(on Layers panel) Select image
```

```
(on Layers panel) Mode->Darken Only
```

```

```

Note that you may have to use "lighten only" first before it will allow you to choose "darken only".

```
</p>
```

```
<page foot>
```

<h4>Mellin-Barnes Integrals</h4>

<p>Many special functions

<m:math display="inline">

<m:mrow>

<m:mi>f</m:mi>

<m:mrow>

<m:mo>(</m:mo>

<m:mi>z</m:mi>

```

 <m:mo>)</m:mo>
 </m:mrow>
</m:mrow>
</m:math> can be represented as a Mellin-Barnes integral, that is,
an integral of a product of gamma functions, reciprocals of gamma
functions, and a power of
<m:math display="inline">
 <m:mi>z</m:mi>
</m:math>, the integration contour being doubly-infinite and eventually
parallel to the imaginary axis. The left-hand side of (

 Integral Equation 1
) is a typical example. By translating the contour parallel to itself
and summing the residues of the integrand, asymptotic expansions of
<m:math display="inline">
 <m:mrow>
 <m:mi>f</m:mi>
 <m:mrow>
 <m:mo>(</m:mo>
 <m:mi>z</m:mi>
 <m:mo>)</m:mo>
 </m:mrow>
 </m:mrow>
 </m:math> for large
<m:math display="inline">
 <m:mrow>
 <m:mo>|</m:mo>
 <m:mi>z</m:mi>
 <m:mo>|</m:mo>
 </m:mrow>
</m:math>, or small
<m:math display="inline">
 <m:mrow>
 <m:mo>|</m:mo>
 <m:mi>z</m:mi>
 <m:mo>|</m:mo>
 </m:mrow>
</m:math>, can be obtained complete with an integral representation of the
error term.
</p>

 </dlmfpolygammafunctions.xhtml>

```

$\psi_n(z)$ , are called the *polygamma functions*. In particular,
$$\psi_n(z) = \frac{d^{n+1}}{dz^{n+1}} \ln \Gamma(z)$$
 $\psi_n(z)$  is the *trigamma function*;
$$\psi_n(z) = \frac{d^{n+1}}{dz^{n+1}} \ln \Gamma(z)$$
 $\psi_n(z)$ ,
$$\psi_n(z) = \frac{d^{n+1}}{dz^{n+1}} \ln \Gamma(z)$$
 $\psi_n(z)$  are the *tetra-*, *penta-* and *hexagamma functions* respectively. Most properties of these functions follow straightforwardly by differentiation of properties of the  $\psi$  function. This includes asymptotic expansions.

```

 Digital Library of Mathematical Functions

 The Gamma Function -- Tables
 </div>
 <hr/>
 <h3>Tables</h3>

```

These tables show Axiom's compliance with published standard values. In all cases shown here Axiom conforms to the accuracy of the published tables.

```

 The Gamma Function
 The Psi Function

```

```

<h4>The Gamma Function</h4>

```

This table was constructed from the published values in the Handbook of Mathematical Functions, by Milton Abramowitz and Irene A. Stegun, by Dover (1965), pp 267-270.

The first column is the point where the Gamma function is evaluated. The second column is the value reported in the Handbook. The third column is the actual value computed by Axiom at the given point. The fourth column is the difference of Axiom's value and the Handbook value.

```

#### <h4>The Psi Function</h4>

This table was constructed from the published values in the Handbook of Mathematical Functions, by Milton Abramowitz and Irene A. Stegun, by Dover (1965), pp 267-270.

Axiom implements the polygamma function which allows for multiple derivatives. The Psi function is a special case of the polygamma function for zero derivatives. For the purpose of this table it is defined as:

```
<pre>
 Psi(x) == polygamma(0,x)
</pre>
```

The first column is the point where the Gamma function is evaluated. The second column is the value reported in the Handbook. The third column is the actual value computed by Axiom at the given point. The fourth column is the difference of Axiom's value and the Handbook value.

```

 <body onload="resetvars();">
 <page head>
 <div align="center">Solution of Differential Equations</div>
 <hr/>

```

In this section we discuss Axiom's facilities for solving differential equations in closed-form and in series.

Axiom provides facilities for closed-form solution of single differential equations of the following kinds:

```

 linear ordinary differential equations

 non-linear first order ordinary differential equations when integrating
 factors can be found just by integration

```

For a discussion of the solution of systems of linear and polynomial equations, see <a href="axbook/section-8.5.xhtml">Solution of Linear and Polynomial Equations</a>.

```

 Closed-Form Solutions of Linear Differential Equations

 Closed-Form Solutions of Non-Linear Differential Equations

 Power Series Solutions of Differential Equations

```

 </script>
 </head>
 <body onload="resetvars();">
 <page head>
 <div align="center">
 Closed-Form Solutions of Linear Differential Equations
 </div>
 <hr/>
 A differential equation is an equation involving an unknown function and
 one or more of its derivatives. The equation is called ordinary if
 derivatives with respect to only one dependent variable appear in the
 equation (it is called partial otherwise). The package
 ElementaryFunctionODESolver
 provides the top-level operation
 solve for finding closed-form solutions of
 ordinary differential equations.

```

To solve a differential equation, you must first create an operator for the unknown function. We let  $y$  be the unknown function in terms of  $x$ .

```

 <input type="submit" id="p1" class="subbut"
 onclick="makeRequest('p1');"
 value="y:=operator 'y" />
 <div id="ansp1"><div></div></div>

```

You then type the equation using `<a href="dbopd.xhtml">D</a>` to create the derivatives of the unknown function  $y(x)$  where  $x$  is any symbol you choose (the so-called dependent variable). This is how you enter the equation

```

<pre>
 y'' + y' + y = 0
</pre>

 <input type="submit" id="p2" class="subbut"
 onclick="handleFree(['p1','p2']);"
 value="deq:=D(y x,x,2)+D(y x,x)+y x=0" />
 <div id="ansp2"><div></div></div>

```

```

```

```

```

The simplest way to invoke the `<a href="dbopsolve.xhtml">solve</a>` command is with three arguments,

```

```

```
the differential equation
```

```
the operator representing the unknown function
```

```
the dependent variable
```

```

```

So, to solve the above equation, we enter this.

```

```

```

```

```
<input type="submit" id="p3" class="subbut"
 onclick="handleFree(['p1','p2','p3']);"
 value="solve(deq,y,x)" />
```

```
<div id="ansp3"><div></div></div>
```

```

```

```

```

Since linear ordinary differential equations have infinitely many solutions, `<a href="dbopsolve.xhtml">solve</a>` returns a particular solution  $f_p$  and a basis  $f_1, \dots, f_n$  for the solutions of the corresponding homogeneous equation. Any expression of the form  $f_p + c_1 f_1 + \dots + c_n f_n$  where the  $c_i$  do not involve the dependent variable is also a solution. This is similar to what you get when you solve systems of linear algebraic equations.

A way to select a unique solution is to specify initial conditions: choose a value  $a$  for the dependent variable and specify the values of the unknown function and its derivatives at  $a$ . If the number of initial conditions is equal to the order of the equation, then the solution is unique (if it exists in closed form) and `<a href="dbopsolve.xhtml">solve</a>` tries to find it. To specify initial conditions to `<a href="dbopsolve.xhtml">solve</a>`, use an `<a href="db.xhtml?Equation">Equation</a>` of the form  $x=a$  for the third parameter instead of the dependent variable, and add a fourth parameter consisting of the list of values  $y(a)$ ,  $y'(a)$ , ...

To find the solution of  $y'' + y = 0$  satisfying  $y(0) = y'(0) = 1$ , do this.

```

```

```

```

```
<input type="submit" id="p4" class="subbut"
 onclick="handleFree(['p1','p4']);"
 value="deq:=D(y x,x,2)+y x" />
```

```
<div id="ansp4"><div></div></div>
```

```

```

```

```

You can omit the `"=0"` when you enter the equation to be solved.

```

```

```

 <input type="submit" id="p5" class="subbut"
 onclick="handleFree(['p1','p4','p5']);"
 value="solve(deq,y,x=0,[1,1])" />
 <div id="ansp5"><div></div></div>

```

Axiom is not limited to linear differential equations with constant coefficients. It can also find solutions when the coefficients are rational or algebraic functions of the dependent variable. Furthermore, Axiom is not limited by the order of the equation. Axiom can solve the following third order equations with polynomial coefficients.

```

 <input type="submit" id="p6" class="subbut"
 onclick="handleFree(['p1','p6']);"
 value="deq:=x^3*D(y x,x,3)+x^2*D(y x,x,2)-2*x*D(y x,x)+2*yx=2*x^4" />
 <div id="ansp6"><div></div></div>

 <input type="submit" id="p7" class="subbut"
 onclick="handleFree(['p1','p6','p7']);"
 value="solve(deq,y,x)" />
 <div id="ansp7"><div></div></div>

```

On the other hand, and in contrast with the operation [integrate](dbopintegrate.xhtml) it can happen that Axiom finds no solution and that some closed-form solution still exists. While it is mathematically complicated to describe exactly when the solutions are guaranteed to be found, the following statements are correct and form good guidelines for linear ordinary differential equations.

```

 If the coefficients are constants, Axiom finds a complete basis of
 solutions (i.e. all solutions).

 If the coefficients are rational functions in the dependent variable,
 Axiom at least finds all solutions that do not involve algebraic
 functions.

```

Note that this last statement does not mean that Axiom does not find the solutions that are algebraic functions. It means that it is not guaranteed that the algebraic function solutions will be found. This is an example where all the algebraic solutions are found.

```

```

```

 <input type="submit" id="p8" class="subbut"
 onclick="handleFree(['p1','p8']);"
 value="deq:=(x^2+1)*D(y x,x,2)+3*x*D(y x,x)+y x=0" />
 <div id="ansp8"><div></div></div>

 <input type="submit" id="p9" class="subbut"
 onclick="handleFree(['p1','p8','p9']);"
 value="solve(deq,y,x)" />
 <div id="ansp9"><div></div></div>

```

*<page foot>*

## 1.9.326 equidifferentialnonlinear.xhtml

```

<equidifferentialnonlinear.xhtml>≡
 <standard head>
 <script type="text/javascript">
 <handlefreevars>
 <axiom talker>
 </script>
 </head>
 <body onload="resetvars();">
 <page head>
 <div align="center">
 Closed-Form Solutions of Non-Linear Differential Equations
 </div>
 <hr/>

```

This is an example that shows how to solve a non-linear first order ordinary differential equation manually when an integrating factor can be found just by integration. At the end, we show you how to solve it directly.

Let's solve the differential equation

```

<pre>
 y' = y/(x + y log y)
</pre>

```

Using the notation

```

<pre>
 m(x,y)+n(x,y)y' = 0
</pre>

```

we have  $m=-y$  and  $n=x+y\log y$

```

 <input type="submit" id="p1" class="subbut"
 onclick="makeRequest('p1');"
 value="m:=-y" />
 <div id="ansp1"><div></div></div>

 <input type="submit" id="p2" class="subbut"
 onclick="handleFree(['p1','p2']);"
 value="n:=x+y*log y" />
 <div id="ansp2"><div></div></div>

```

We first check for exactness, that is, does  $dm/dy=dn/dx$ ?

```

 <input type="submit" id="p3" class="subbut"
 onclick="handleFree(['p1','p2','p3']);"
 value="D(m,y)-D(n,x)" />
 <div id="ansp3"><div></div></div>

```

This is not zero, so the equation is not exact. Therefore we must look for an integrating factor, that is, a function  $\mu(x,y)$  such that  $d(\mu m)/dy = d(\mu n)/dx$ . Normally, we first search for  $\mu(x,y)$  depending only on  $x$  or only on  $y$ . Let's search for such a  $\mu(x)$  first.

```

 <input type="submit" id="p4" class="subbut"
 onclick="makeRequest('p4');"
 value="mu:=operator 'mu'" />
 <div id="ansp4"><div></div></div>

 <input type="submit" id="p5" class="subbut"
 onclick="handleFree(['p1','p2','p4','p5']);"
 value="a:=D(mu(x)*m,y)-D(mu(x)*n,x)" />
 <div id="ansp5"><div></div></div>

```

If the above is zero for a function  $\mu$  that does not depend on  $y$ , then  $\mu(x)$  is an integrating factor.

```

 <input type="submit" id="p6" class="subbut"
 onclick="handleFree(['p1','p2','p4','p5','p6']);"
 value="solve(a=0,mu,x)" />
 <div id="ansp6"><div></div></div>

```

The solution depends on  $y$ , so there is no integrating factor that depends on  $x$  only. Let's look for one that depends on  $y$  only.

```

 <input type="submit" id="p7" class="subbut"
 onclick="handleFree(['p1','p2','p4','p7']);"
 value="b:=D(mu(y)*m,y)-D(mu(y)*n,x)" />
 <div id="ansp7"><div></div></div>

```

```

 <input type="submit" id="p8" class="subbut"
 onclick="handleFree(['p1','p2','p4','p7','p8']);"
 value="sb:=solve(b=0,mu,y)" />
 <div id="ansp8"><div></div></div>

```

We've found one. The above  $\mu(y)$  is an integrating factor. We must multiply our initial equation (that is,  $m$  and  $n$ ) by the integrating factor.

```

 <input type="submit" id="p9" class="subbut"
 onclick="handleFree(['p1','p2','p4','p7','p8','p9']);"
 value="intFactor:=sb.basis.1" />
 <div id="ansp9"><div></div></div>

 <input type="submit" id="p10" class="subbut"
 onclick="handleFree(['p1','p2','p4','p7','p8','p9','p10']);"
 value="m:=intFactor*m" />
 <div id="ansp10"><div></div></div>

 <input type="submit" id="p11" class="subbut"
 onclick="handleFree(['p1','p2','p4','p7','p8','p9','p11']);"
 value="n:=intFactor*n" />
 <div id="ansp11"><div></div></div>

```

Let's check for exactness.

```

 <input type="submit" id="p12" class="subbut"
 onclick="handleFree(['p1','p2','p4','p7','p8','p9','p10','p11','p12']);"
 value="D(m,y)-D(n,x)" />
 <div id="ansp12"><div></div></div>

```

We must solve the exact equation, that is, find a function  $s(x,y)$  such that  $ds/dx=m$  and  $ds/dy=n$ . We start by writing

```

<pre>
 s(x,y) = h(y) + integrate(m,x)
</pre>

```

where  $h(y)$  is an unknown function of  $y$ . This guarantees that  $ds/dx=m$ .

```

 <input type="submit" id="p13" class="subbut"
 onclick="makeRequest('p13');"
 value="h:=operator 'h'" />
 <div id="ansp13"><div></div></div>

 <input type="submit" id="p14" class="subbut"
 onclick="handleFree(['p1','p2','p4','p7','p8','p9','p10','p13','p14']);"
 value="sol:=h y+integrate(m,x)" />
 <div id="ansp14"><div></div></div>

```

All we want is to find  $h(y)$  such that  $ds/dy=n$ .

```

 <input type="submit" id="p15" class="subbut"
 onclick=
 "handleFree(['p1','p2','p4','p7','p8','p9','p10','p13','p14','p15']);"
 value="dsol:=D(sol,y)" />
 <div id="ansp15"><div></div></div>

 <input type="submit" id="p16" class="subbut"
 onclick=
 "handleFree(['p1','p2','p4','p7','p8','p9','p10','p13','p14','p15','p16']);"
 value="nsol:=solve(dsol=n,h,y)" />
 <div id="ansp16"><div></div></div>

```

The above particular solution is the  $h(y)$  we want, so we just replace  $h(y)$  by it in the implicit solution.

```

 <input type="submit" id="p17" class="subbut"
 onclick=
 "handleFree(['p1','p2','p4','p7','p8','p9','p10','p13','p14','p15','p16','p17']);"
 value="eval(sol,h y=nsol.particular)" />
 <div id="ansp17"><div></div></div>

```

A first integral of the initial equation is obtained by setting this result equal to an arbitrary constant.

Now that we've seen how to solve the equation "by hand" we show you how to do it with the `<a href="dbopsolve.xhtml">solve</a>` operation. First define `y` to be an operator.

```

 <input type="submit" id="p18" class="subbut"
 onclick="makeRequest('p18');"
 value="y:=operator 'y'" />
 <div id="ansp18"><div></div></div>

```

Next we create the differential equation.

```

 <input type="submit" id="p19" class="subbut"
 onclick="handleFree(['p18','p19']);"
 value="deq:=D(y x,x)=y(x)/(x+y(x)*log y x)" />
 <div id="ansp19"><div></div></div>

```

Finally, we solve it.

```

 <input type="submit" id="p20" class="subbut"
 onclick="handleFree(['p18','p19','p20']);"
 value="solve(deq,y,x)" />
 <div id="ansp20"><div></div></div>

```

*<page foot>*

### 1.9.327 equidifferentialpowerseries.xhtml

```

<equidifferentialpowerseries.xhtml>≡
 <standard head>
 <script type="text/javascript">
 <handlefreevars>
 <axiom talker>
 </script>
 </head>
 <body onload="resetvars();">
 <page head>
 <div align="center">
 Power Series Solutions of Differential Equations
 </div>
 <hr/>

```

The command to solve differential equations in power series around a particular initial point with specific initial conditions is called `<a href="dbopseriesolve.xhtml">seriesSolve</a>`. It can take a variety of parameters, so we illustrate its use with some examples.

Since the coefficients of some solutions are quite large, we reset the default to compute only seven terms.

```

 <input type="submit" id="p1" class="noresult"
 onclick="makeRequest('p1');"
 value=")set streams calculate 7" />
 <div id="ansp1"><div></div></div>

```

You can solve a single nonlinear equation of any order. For example, we solve

```

<pre>
 y''' = sin(y'') * exp(y) + cos(x)
</pre>
subject to y(0)=1, y'(0)=0, y''(0)=0

```

We first tell Axiom that the symbol 'y denotes a new operator.

```

 <input type="submit" id="p2" class="subbut"
 onclick="makeRequest('p2');"
 value="y:=operator 'y" />
 <div id="ansp2"><div></div></div>

```

Enter the differential equation using y like any system function.

```

 <input type="submit" id="p3" class="subbut"
 onclick="handleFree(['p1','p2','p3']);"
 value="eq:=D(y(x),x,3)-sin(D(y(x),x,2))*exp(y(x))=cos(x)" />
 <div id="ansp3"><div></div></div>

```

Solve it around x=0 with the initial conditions y(0)=1, y'(0)=y''(0)=0.

```

 <input type="submit" id="p4" class="subbut"
 onclick="handleFree(['p1','p2','p3','p4']);"
 value="seriesSolve(eq,y,x=0,[1,0,0])" />
 <div id="ansp4"><div></div></div>

```

You can also solve a system of nonlinear first order equations. For example, we solve a system that has tan(t) and sec(t) as solutions.

We tell Axiom that x is also an operator.

```

 <input type="submit" id="p5" class="subbut"
 onclick="makeRequest('p5');"
 value="x:=operator 'x'" />
 <div id="ansp5"><div></div></div>

```

Enter the two equations forming our system.

```

 <input type="submit" id="p6" class="subbut"
 onclick="handleFree(['p5','p6']);"
 value="eq1:=D(x(t),t)=1+x(t)^2" />
 <div id="ansp6"><div></div></div>

 <input type="submit" id="p7" class="subbut"
 onclick="handleFree(['p2','p5','p7']);"
 value="eq2:=D(y(t),t)=x(t)*y(t)" />
 <div id="ansp7"><div></div></div>

```

Solve the system around t=0 with the initial conditions x(0)=0 and y(0)=1. Notice that since we give the unknowns in the order [x,y], the answer is a

list of two series in the order [series for  $x(t)$ , series for  $y(t)$ ].

```

```

```

```

```
<input type="submit" id="p8" class="subbut"
```

```
 onclick="handleFree(['p1','p2','p5','p6','p7','p8']);"
```

```
 value="seriesSolve([eq2,eq1],[x,y],t=0,[y(0)=1,x(0)=0])" />
```

```
<div id="ansp8"><div></div></div>
```

```

```

```

```

The order in which we give the equations and the initial conditions has no effect on the order of the solution.

*<page foot>*

## 1.9.329 equsystemlinear.xhtml

```

<equsystemlinear.xhtml>≡
 <standard head>
 <script type="text/javascript">
 <handlefreevars>
 <axiom talker>
 </script>
 </head>
 <body onload="resetvars();">
 <page head>
 <div align="center">Solution of Systems of Linear Equations</div>
 <hr/>
 You can use the operation solve to solve
 systems of linear equations.

```

The operation `<a href="dbopsolve.xhtml">solve</a>` takes two arguments, the list of equations and the list of the unknowns to be solved for. A system of linear equations need not have a unique solution.

To solve the linear system:

```

<pre>
 x + y + x = 8
 3*x - 2*y + z = 0
 x + 2*y + 2*z = 17
</pre>

```

evaluate this expression.

```

 <input type="submit" id="p1" class="subbut"
 onclick="makeRequest('p1');"
 value="solve([x+y+x=8,3*x-2*y+z=0,x+2*y+2*z=17],[x,y,z])" />
 <div id="ansp1"><div></div></div>

```

Parameters are given as new variables starting with a percent sign and "%" and the variables are expressed in terms of the parameters. If the system has no solutions then the empty list is returned.

When you solve the linear system

```

<pre>
 x + 2*y + 3*z = 2
 2*x + 3*y + 4*z = 2
 3*x + 4*y + 5*z = 2
</pre>

```

with this expression you get a solution involving a parameter.

```

 <input type="submit" id="p2" class="subbut"
 onclick="makeRequest('p2');"
 value="solve([x+2*y+3*z=2,2*x+3*y+4*z=2,3*x+4*y+5*z=2],[x,y,z])" />
 <div id="ansp2"><div></div></div>

```

The system can also be presented as a matrix and a vector. The matrix contains the coefficients of the linear equations and the vector contains the numbers appearing on the right-hand sides of the equations. You may input the matrix as a list of rows and the vector as a list of its elements.

To solve the system:

```

<pre>
 x + y + z = 8
 2*x - 2*y + z = 0
 x + 2*y + 2*z = 17
</pre>

```

in matrix form you would evaluate this expression.

```

 <input type="submit" id="p3" class="subbut"
 onclick="makeRequest('p3');"
 value="solve([[1,1,1],[3,-2,1],[1,2,2]],[8,0,17])" />
 <div id="ansp3"><div></div></div>

```

The solutions are presented as a Record with two components: the component particular contains a particular solution of the given system or the item "failed" if there are no solutions, the component basis contains a list of vectors that are a basis for the space of solutions of the corresponding homogeneous system. If the system of linear equations does not have a unique solution, then the basis component contains non-trivial vectors.

This happens when you solve the linear system

```

<pre>
 x + 2*y + 3*z = 2
 2*x + 3*y + 4*z = 2
 3*x + 4*y + 5*z = 2
</pre>

```

with this command.

```

 <input type="submit" id="p4" class="subbut"
 onclick="makeRequest('p4');"

```

```

 value="solve([[1,2,3],[2,3,4],[3,4,5]],[2,2,2])" />
 <div id="ansp4"><div></div></div>

```

All solutions of this system are obtained by adding the particular solution with a linear combination of the basis vectors.

When no solution exists then "failed" is returned as the particular component, as follows:

```

 <input type="submit" id="p5" class="subbut"
 onclick="makeRequest('p5');"
 value="solve([[1,2,3],[2,3,4],[3,4,5]],[2,3,2])" />
 <div id="ansp5"><div></div></div>

```

When you want to solve a system of homogeneous equations (that is, a system where the numbers on the right-hand sides of the equations are all zero) in the matrix form you can omit the second argument and use the [nullSpace](dbopnullspace.xhtml) operation.

This computes the solutions of the following system of equations:

```

<pre>
 x + 2*y + 3*z = 0
 2*x + 3*y + 4*z = 0
 3*x + 4*y + 5*z = 0
</pre>

```

The result is given as a list of vectors and these vectors form a basis for the solution space.

```

 <input type="submit" id="p6" class="subbut"
 onclick="makeRequest('p6');"
 value="nullSpace([[1,2,3],[2,3,4],[3,4,5]])" />
 <div id="ansp6"><div></div></div>

```

<standard head>
 <script type="text/javascript">
 <handlefreevars>
 <axiom talker>
 </script>
</head>
<body onload="resetvars();">
 <page head>
 <div align="center">Algebraic Functions</div>
 <hr/>

```

Algebraic functions are functions defined by algebraic equations. There are two ways of constructing them, either by using rational powers or implicitly. For rational powers, use [\\*\\*](dbopstarstar.xhtml) or the system functions [sqrt](dbopsqrt.xhtml) and [nthRoot](dbopnthroot.xhtml) for square and nth roots.

```

 <input type="submit" id="p1" class="subbut"
 onclick="makeRequest('p1');"
 value="f:=sqrt(1+x^(1/3))" />
 <div id="ansp1"><div></div></div>

```

To define an algebraic function implicitly use

[rootOf](dboprootof.xhtml). The following line defines a function  $y$  of  $x$  satisfying the equation

```

<pre>
 y^3 = x*y-y^2-x^3+1
</pre>

```

```

 <input type="submit" id="p2" class="subbut"
 onclick="makeRequest('p2');"
 value="y:=rootOf(y^3+y^2-x*y+x^3-1,y)" />
 <div id="ansp2"><div></div></div>

```

You can manipulate, differentiate or integrate an implicitly defined algebraic function like any other Axiom function.

```

 <input type="submit" id="p3" class="subbut"
 onclick="handleFree(['p2','p3']);"

```

```

 value="differentiate(y,x)" />
 <div id="ansp3"><div></div></div>

```

Higher powers of algebraic functions are automatically reduced during calculations.

```

 <input type="submit" id="p4" class="subbut"
 onclick="handleFree(['p2','p4']);"
 value="(y+1)^3" />
 <div id="ansp4"><div></div></div>

```

But denominators are not automatically rationalized.

```

```

Axiom has most of the usual functions from calculus built-in.

```

 <input type="submit" id="p1" class="subbut"
 onclick="makeRequest('p1');"
 value="f:=x*log y * sin(1/(x+y))" />
 <div id="ansp1"><div></div></div>

```

You can substitute values or another elementary function for variables with the function eval.

```

 <input type="submit" id="p2" class="subbut"
 onclick="handleFree(['p1','p2']);"
 value="eval(f,[x=y,y=x])" />
 <div id="ansp2"><div></div></div>

```

As you can see, the substitutions are made "in parallel" as in the case of polynomials. It's also possible to substitute expressions for kernels instead of variables.

```

 <input type="submit" id="p3" class="subbut"
 onclick="handleFree(['p1','p3']);"
 value="eval(f,log y = acosh(x+sqrt y))" />
 <div id="ansp3"><div></div></div>

<page foot>
```

### 1.9.335 funoperatoralgebra.xhtml

*(funoperatoralgebra.xhtml)*  $\equiv$

```

<standard head>
 <script type="text/javascript">
 <handlefreevars>
 <axiom talker>
 </script>
</head>
<body onload="resetvars();">
 <page head>
 <div align="center">Operator</div>
 <hr/>

```

Given any ring  $R$ , the ring of the [Integer](db.xhtml?Integer) linear operators over  $R$  is called [Operator\( \$R\$ \)](db.xhtml?Operator). To create an operator over  $R$ , first create a basic operator using the operation [operator](dbopoperator.xhtml), and then convert it to [Operator\( \$R\$ \)](db.xhtml?Operator) for the  $R$  you want. We choose  $R$  to be the two by two matrices over the integers.

```

 <input type="submit" id="p1" class="subbut"
 onclick="makeRequest('p1');"
 value="R:=SQMATRIX(2,INT)" />
 <div id="ansp1"><div></div></div>

```

Create the operator tilde on  $R$

```

 <input type="submit" id="p2" class="subbut"
 onclick="handleFree(['p1','p2']);"
 value='t:=operator("tilde")::OP(R)' />
 <div id="ansp2"><div></div></div>

```

Since [Operator](db.xhtml?Operator) is unexposed we must either package-call operations from it, or expose it explicitly. For convenience we will do the latter.

```

 <input type="submit" id="p3" class="noresult"
 onclick="makeRequest('p3');"
 value=")set expose add constructor Operator" />
 <div id="ansp3"><div></div></div>

```

</ul>

To attach an evaluation function (from  $R$  to  $R$ ) to an operator over  $R$ , use `evaluate(op,f)` where `op` is an operator over  $R$  and `f` is a function  $R \rightarrow R$ . This needs to be done only once when the operator is defined. Note that `f` must be `<a href="db.xhtml?Integer">Integer</a>` linear (that is,

<pre>

$f(ax+y) = a f(x) + f(y)$

</pre>

for any integer  $a$  and any  $x$  and  $y$  in  $R$ ). We now attach the transpose map to the above operator `t`.

<ul>

<li>

`<input type="submit" id="p4" class="subbut" onclick="handleFree(['p1','p2','p3','p4']);" value="evaluate(t,m+>transpose m)" />`  
`<div id="ansp4"><div></div></div>`

</li>

</ul>

Operators can be manipulated formally as in any ring:

`<a href="dbopplus.xhtml">+</a>` is the pointwise addition and

`<a href="dbopstar.xhtml">*</a>` is composition. Any element  $x$  of  $R$  can be converted to an operator `op_x` over  $R$ , and the evaluation function of `op_x` is left-multiplication by  $x$ . Multiplying on the left by this matrix swaps the two rows.

<ul>

<li>

`<input type="submit" id="p5" class="subbut" onclick="handleFree(['p1','p2','p3','p4','p5']);" value="s:R:=matrix [[0,1],[1,0]]" />`  
`<div id="ansp5"><div></div></div>`

</li>

</ul>

Can you guess what is the action of the following operator?

<ul>

<li>

`<input type="submit" id="p6" class="subbut" onclick="handleFree(['p1','p2','p3','p4','p5','p6']);" value="rho:=t*s" />`  
`<div id="ansp6"><div></div></div>`

</li>

</ul>

Hint: applying `rho` four times gives the identity, so `rho^4-1` should return 0 when applied to any two by two matrix.

<ul>

<li>

`<input type="submit" id="p7" class="subbut"`

```

 onclick="handleFree(['p1','p2','p3','p4','p5','p6','p7']);"
 value="z:=rho^4-1" />
 <div id="ansp7"><div></div></div>

Now check with this matrix

 <input type="submit" id="p8" class="subbut"
 onclick="handleFree(['p1','p2','p3','p4','p8']);"
 value="m:R:=matrix [[1,2],[3,4]]" />
 <div id="ansp8"><div></div></div>

 <input type="submit" id="p9" class="subbut"
 onclick="handleFree(['p1','p2','p3','p4','p5','p6','p7','p8','p9']);"
 value="z m" />
 <div id="ansp9"><div></div></div>

```

As you have probably guessed by now,  $\rho$  acts on matrices by rotating the elements clockwise.

```

 <input type="submit" id="p10" class="subbut"
 onclick="handleFree(['p1','p2','p3','p4','p5','p6','p8','p10']);"
 value="rho m" />
 <div id="ansp10"><div></div></div>

 <input type="submit" id="p11" class="subbut"
 onclick="handleFree(['p1','p2','p3','p4','p5','p6','p8','p11']);"
 value="rho rho m" />
 <div id="ansp11"><div></div></div>

 <input type="submit" id="p12" class="subbut"
 onclick="handleFree(['p1','p2','p3','p4','p5','p6','p8','p12']);"
 value="(rho**3) m" />
 <div id="ansp12"><div></div></div>

```

Do the swapping of rows and transposition commute? We can check by computing their bracket.

```

```

```

<div></div></div>

Now apply it to m.

<div></div></div>

```

Next we demonstrate how to define a differential operator on a polynomial ring. This is the recursive definition of the  $n$ th Legendre polynomial.

```

<div></div></div>

```

Create the differential operator  $d/dx$  on polynomials in  $x$  over the rational numbers.

```

<div></div></div>

```

Now attach a map to it.

```

<div></div></div>

```

This is the differential equation satisfied by the  $n$ th Legendre polynomial.

```

 <input type="submit" id="p18" class="noresult"
 onclick="handleFree(['p1','p2','p3','p16','p17','p18']);"
 value="E n == (1-x^2)*dx^2-2*x*dx+n*(n+1)" />
 <div id="ansp18"><div></div></div>

```

Now we verify this for  $n=15$ . Here is the polynomial.

```

 <input type="submit" id="p19" class="subbut"
 onclick="handleFree(['p1','p2','p3','p15','p19']);"
 value="L 15" />
 <div id="ansp19"><div></div></div>

```

Here is the operator.

```

 <input type="submit" id="p20" class="subbut"
 onclick="handleFree(['p1','p2','p3','p16','p17','p18','p20']);"
 value="E 15" />
 <div id="ansp20"><div></div></div>

```

Here is the evaluation.

```

 <input type="submit" id="p21" class="subbut"
 onclick=
 "handleFree(['p1','p2','p3','p15','p16','p17','p18','p19','p20','p21']);"
 value="(E 15)(L 15)" />
 <div id="ansp21"><div></div></div>

```

## 1.9.337 funpatternmatching.xhtml

*<funpatternmatching.xhtml>*≡

```

<standard head>
 <script type="text/javascript">
<handlefreevars>
<axiom talker>
 </script>
</head>
<body onload="resetvars();">
<page head>
 <div align="center">Rules and Pattern Matching</div>
 <hr/>

```

A common mathematical formula is

```

<pre>
log(x)+log(y)==log(x*y)
</pre>

```

for any x and y. The presence of the word "any" indicates that x and y can stand for arbitrary mathematical expressions in the above formula. You can use such mathematical formulas in Axiom to specify "rewrite rules". Rewrite rules are objects in Axiom that can be assigned to variables for later use, often for the purpose of simplification. Rewrite rules look like ordinary function definitions except that they are preceded by the reserved word rule. For example, a rewrite rule for the above formula is:

```

<pre>
rule log(x) + log(y) == log(x * y)
</pre>

```

Like function definitions, no action is taken when a rewrite rule is issued. Think of rewrite rules as functions that take one argument. When a rewrite rule A=B is applied to an argument f, its meaning is "rewrite every subexpressions of f that matches A by B". The left-and side of a rewrite rule is called a [pattern](glossarypage.xhtml#p38600); its right-hand side is called its [substitution](glossarypage.xhtml#p49000).

Create a rewrite rule named logrule. The generated symbol begins with a "%" and is a place holder for any other terms that might occur in the sum.

```

 <input type="submit" id="p1" class="subbut"
 onclick="makeRequest('p1');"
 value="logrule:=rule log(x)+log(y)==log(x*y)" />
 <div id="ansp1"><div></div></div>

```

Create an expression with logarithms.

```

 <input type="submit" id="p2" class="subbut"
 onclick="makeRequest('p2');"
 value="f:=log sin x + log x" />
 <div id="ansp2"><div></div></div>

```

Apply logrule to f.

```

 <input type="submit" id="p3" class="subbut"
 onclick="handleFree(['p1','p2','p3']);"
 value="logrule f" />
 <div id="ansp3"><div></div></div>

```

The meaning of our example rewrite rule is "for all expressions x and y, rewrite  $\log(x)$  and  $\log(y)$  by  $\log(x*y)$ ". Patterns generally have both operation names

(here, [log](dboplog.xhtml) and [+](dbopplus.xhtml)) and variables (here, x and y). By default, every operation name stands for itself. The [log](dboplog.xhtml) matches only "log" and not any other operation such as [sin](dbopsin.xhtml). On the other hand, variables do not stand for themselves. Rather, a variable denotes a [pattern variable](glossarypage.xhtml#p39400) that is free to match any expression whatsoever.

When a rewrite rule is applied, a process called [pattern matching](glossarypage.xhtml#p38661) goes to work by systematically scanning the subexpressions of the argument. When a subexpression is found that "matches" the pattern, the subexpression is replaced by the right hand side of the rule. The details of what happens will be covered later.

The customary Axiom notation for patterns is actually a shorthand for a longer, more general notation. Pattern variables can be made explicit by using a percent ("%") as the first character of the variable name. To say that a name stands for itself, you can prefix that name with a quote operator (""). Although the current Axiom parser does not let you quote an operation name, this more general notation gives you an alternative way of giving the same rewrite rule:

```

<pre>
 rule log(%x) + log(%y) == log(x*y)
</pre>

```

This longer notation gives you patterns that the standard notation won't

handle. For example, the rule

```
<pre>
 rule %f(c * 'x) == c*f(x)
</pre>
```

means "for all f and c, replace f(y) by c\*f(x) when y is the product of c and the explicit variable x".

Thus the pattern can have several adornments on the names that appear there. Normally, all of these adornments are dropped in the substitution on the right hand side. To summarize:

---

To enter a single rule in Axiom, use the following syntax:

```
<pre>
 rule lefthandside == righthandside
</pre>
```

The lefthandside is a pattern to be matched and the righthandside is its substitution. The rule is an object of type

[RewriteRule](db.xhtml?RewriteRule) that can be assigned to a variable and applied to expressions to transform them.

---

Rewrite rules can be collected into rulesets so that a set of rules can be applied at once. Here is another simplification rule for logarithms.

```
<pre>
 rule y*log(x) == log(x**y)
</pre>
```

for any x and y. If instead of giving a single rule following the reserved word rule you give a "pile" of rules, you create what is called a ruleset. Like rules, rulesets are objects in Axiom and can be assigned to variables. You will find it useful to group commonly used rules into input files, and read them in as needed. Create a ruleset named logrules.

```

 <input type="submit" id="p4" class="subbut"
 onclick="makeRequest('p4');"
 value="logrules:=rule (log(x)+log(y)==log(x*y) ; y*log(x)==log(x^y))" />
 <div id="ansp4"><div></div></div>

```

Again, create an expression f containing logarithms.

```

 <input type="submit" id="p5" class="subbut"
 onclick="makeRequest('p5');"
 value="f:=a*log(sin x)-2*log x" />
 <div id="ansp5"><div></div></div>

```

```

```

Apply the ruleset logrules to f.

```

```

```

```

```
<input type="submit" id="p6" class="subbut"
 onclick="handleFree(['p4','p5','p6']);"
 value="logrules f" />
```

```
<div id="ansp6"><div></div></div>
```

```

```

```

```

We have allowed pattern variables to match arbitrary expressions in the above examples. Often you want a variable to match onlyh expressions satisfying some predicate. For example, you may want to apply the transformation

```
<pre>
```

```
y*log(x) == log(x^y)
```

```
</pre>
```

only when y is an integer. The way to restrict a pattern variable y by a predicate f(y) is by using a vertical bar "|", which means "such that", in much the same way it is used in function definitions. You do this only once but at the earliest (meaning deepest and leftmost) part of the pattern. This restricts the logarithmic rule to create integer exponents only.

```

```

```

```

```
<input type="submit" id="p7" class="subbut"
 onclick="makeRequest('p7');"
 value="logrules2:=rule (log(x)+log(y)==log(x*y) ; (y | integer? y)*log(x)==log(x
```

```
<div id="ansp7"><div></div></div>
```

```

```

```

```

Compare this with the result of applying the previous set of rules.

```

```

```

```

```
<input type="submit" id="p8" class="subbut"
 onclick="handleFree(['p5','p8']);"
 value="f" />
```

```
<div id="ansp8"><div></div></div>
```

```

```

```

```

```
<input type="submit" id="p9" class="subbut"
 onclick="handleFree(['p5','p7','p9']);"
 value="logrules2 f" />
```

```
<div id="ansp9"><div></div></div>
```

```

```

```

```

You should be aware that you might need to apply a function like

[integer](dbopinteger.xhtml) within your predicate expression to actually apply the test function. Here we use  
[integer](dbopinteger.xhtml) because  $n$  has type  
[Expression Integer](dbexpressioninteger.xhtml) but  
[even?](dbopevenq.xhtml) is an operation defined on the integers.

```

 <input type="submit" id="p10" class="subbut"
 onclick="makeRequest('p10');"
 value="evenRule:=rule cos(x)^(n | integer? n and even? integer n)==(1-sin(x)^2)^(n/2)" />
 <div id="ansp10"><div></div></div>

```

Here is the application of the rule.

```

 <input type="submit" id="p11" class="subbut"
 onclick="handleFree(['p10','p11']);"
 value="evenRule(cos(x)^2)" />
 <div id="ansp11"><div></div></div>

```

This is an example of some of the usual identities involving products of sines and cosines.

```

 <input type="submit" id="p12" class="subbut"
 onclick="makeRequest('p12');"
 value="sinCosProducts:=rule (sin(x)*sin(y)==(cos(x-y)-cos(x+y))/2 ; cos(x)*cos(y)==(cos(x-y)+cos(x+y))/2)" />
 <div id="ansp12"><div></div></div>

 <input type="submit" id="p13" class="subbut"
 onclick="makeRequest('p13');"
 value="g:=sin(a)*sin(b)+cos(b)*cos(a)+sin(2*z)*cos(2*a)" />
 <div id="ansp13"><div></div></div>

 <input type="submit" id="p14" class="subbut"
 onclick="handleFree(['p12','p13','p14']);"
 value="sinCosProducts g" />
 <div id="ansp14"><div></div></div>

```

Another qualification you will often want to use is to allow a pattern to match an identity element. Using the pattern  $x+y$ , for example, neither  $x$  nor  $y$  matches the expression 0. Similarly, if a pattern contains a product

$x*y$  or an exponentiation  $x^y$ , then neither  $x$  nor  $y$  matches 1. If identical elements were matched, pattern matching would generally loop. Here is an expansion rule for exponentials.

```

 <input type="submit" id="p15" class="subbut"
 onclick="makeRequest('p15');"
 value="exprule:=rule exp(a+b)==exp(a)*exp(b)" />
 <div id="ansp15"><div></div></div>

```

This rule would cause infinite rewriting on this if either  $a$  or  $b$  were allowed to match 0.

```

 <input type="submit" id="p16" class="subbut"
 onclick="handleFree(['p15','p16']);"
 value="exprule exp x" />
 <div id="ansp16"><div></div></div>

```

There are occasions when you do want a pattern variable in a sum or product to match 0 or 1. If so, prefix its name with a "?" whenever it appears in a left-hand side of a rule. For example, consider the following rule for the exponential integral

```
<pre>
 integral((y+exp x)/x,x) == integral(y/x,x)+Ei x
</pre>
```

for any  $x$  and  $y$ . This rule is valid if  $y=0$ . One solution is to create a [Ruleset](db.xhtml?Ruleset) with two rules, one with and one without  $y$ . A better solution is to use an "optional" pattern variable. Define rule `eirule` with a pattern variable `?y` to indicate that an expression may or may not occur.

```

 <input type="submit" id="p17" class="subbut"
 onclick="makeRequest('p17');"
 value="eirule:=rule integral((?y+exp x)/x,x)==integral(y/x,x)+Ei x" />
 <div id="ansp17"><div></div></div>

```

Apply rule `eirule` to an integral without this term.

```

 <input type="submit" id="p18" class="subbut"
 onclick="handleFree(['p17','p18']);"
```

```

 value="eirule integral (exp m/m,m)" />
 <div id="ansp18"><div></div></div>

```

Apply rule eirule to an integral with this term.

```

 <input type="submit" id="p19" class="subbut"
 onclick="handleFree(['p17','p19']);"
 value="eirule integral(sin m+exp m/m,m)" />
 <div id="ansp19"><div></div></div>

```

Here is one final adornment you will find useful. When matching a pattern of the form  $x+y$  to an expression containing a long sum of the form  $a+\dots+b$ , there is no way to predict in advance which subset of the sum matches  $x$  and which matches  $y$ . Aside from efficiency, this is generally unimportant since the rule holds for any possible combination of matches for  $x$  and  $y$ . In some situations, however, you may want to say which pattern variable is a sum (or product) of several terms, and which should match only a single term. To do this, put a prefix colon (":") before the pattern variable that you want to match multiple terms. The remaining rules involve operators  $u$  and  $v$ .

```

 <input type="submit" id="p20" class="subbut"
 onclick="makeRequest('p20');"
 value="u:=operator 'u'" />
 <div id="ansp20"><div></div></div>

```

These definitions tell Axiom that  $u$  and  $v$  are formal operators to be used in expressions.

```

 <input type="submit" id="p21" class="subbut"
 onclick="makeRequest('p21');"
 value="v:=operator 'v'" />
 <div id="ansp21"><div></div></div>

```

First define myRule with no restrictions on the pattern variables  $x$  and  $y$ .

```

 <input type="submit" id="p22" class="subbut"
 onclick="makeRequest('p22');"

```

```

 value="myRule:=rule u(x+y)==u x + v y" />
 <div id="ansp22"><div></div></div>

 Apply myRule to an expression.

 <input type="submit" id="p23" class="subbut"
 onclick="handleFree(['p20','p21','p22','p23']);"
 value="myRule u(a+b+c+d)" />
 <div id="ansp23"><div></div></div>

 Define myOtherRule to match several terms so that the rule gets applied
 recursively.

 <input type="submit" id="p24" class="subbut"
 onclick="makeRequest('p24');"
 value="myOtherRule:=rule u(:x+y)==u x + v y" />
 <div id="ansp24"><div></div></div>

 Apply myOtherRule to the same expression

 <input type="submit" id="p25" class="subbut"
 onclick="handleFree(['p20','p21','p24','p25']);"
 value="myOtherRule u(a+b+c+d)" />
 <div id="ansp25"><div></div></div>

```

Here are some final remarks on pattern matching. Pattern matching provides a very useful paradigm for solving certain classes of problems, namely, those that involve transformations of one form to another and back. However, it is important to recognize its limitations.

First, pattern matching slows down as the number of rules you have to apply increases. Thus it is good practice to organize the sets of rules you use optimally so that irrelevant rules are never included.

Second, careless use of pattern matching can lead to wrong answers. You should avoid pattern matching to handle hidden algebraic relationships that can go undetected by other programs. As a simple example, a symbol such as "J" can easily be used to represent the square root of -1 or some other important algebraic quantity. Many algorithms branch on whether an

expression is zero or not, then divide by that expression if it is not. If you fail to simplify an expression involving powers of  $J$  to  $-1$ , algorithms may incorrectly assume an expression is non-zero, take a wrong branch, and produce a meaningless result.

Pattern matching should also not be used as a substitute for a domain. In Axiom, objects of one domain are transformed to objects of other domains using well-defined [coerce](dbopcoerce.xhtml) operations. Pattern matching should be used on objects that are all of the same type. Thus if your application can be handled by type [Expression](db.xhtml?Expression) in Axiom and you think you need pattern matching consider this choice carefully. You may well be better served by extending an existing domain or by building a new domain of objects for your application.

### 1.9.338 funrationalfunctions.xhtml

```

<funrationalfunctions.xhtml>≡
 <standard head>
 <script type="text/javascript">
 <handlefreevars>
 <axiom talker>
 </script>
 </head>
 <body onload="resetvars();">
 <page head>
 <div align="center">Rational Functions</div>
 <hr/>

```

To create a rational function, just compute the quotient of two polynomials.

```

 <input type="submit" id="p1" class="subbut"
 onclick="makeRequest('p1');"
 value="f:=(x-y)/(x+y)" />
 <div id="ansp1"><div></div></div>

```

Use the functions

<a href="dbopnumber.xhtml">number</a> and  
 <a href="dbopdenom.xhtml">denom</a> to recover the numerator and denominator of a fraction:

```

 <input type="submit" id="p2" class="subbut"
 onclick="handleFree(['p1','p2']);"
 value="numer f" />
 <div id="ansp2"><div></div></div>

 <input type="submit" id="p3" class="subbut"
 onclick="handleFree(['p1','p3']);"
 value="denom f" />
 <div id="ansp3"><div></div></div>

```

Since these are polynomials, you can apply all of the

<a href="polynomialpage.xhtml">polynomial operations</a> to them.

You can substitute values or other rational functions for the variables

using the function <a href="dbopeval.xhtml">eval</a>. The syntax for

<a href="dbopeval.xhtml">eval</a> is similar to the one for polynomials:

```

 <input type="submit" id="p4" class="subbut"
 onclick="handleFree(['p1','p4']);"
 value="eval(f,x=1/x)" />
 <div id="ansp4"><div></div></div>

 <input type="submit" id="p5" class="subbut"
 onclick="handleFree(['p1','p5']);"
 value="eval(f,[x=y,y=x])" />
 <div id="ansp5"><div></div></div>

<page foot>
```

### 1.9.339 funsimplication.xhtml

```

<funsimplication.xhtml>≡
 <standard head>
 <script type="text/javascript">
 <handlefreevars>
 <axiom talker>
 </script>
 </head>
 <body onload="resetvars();">
 <page head>
 <div align="center">Simplification</div>
 <hr/>

```

Simplifying an expression often means different things at different times. Axiom offers a large number of "simplification" functions. The most common one, which performs the usual trigonometric simplifications is

[simplify](dbopsimplify.xhtml).

```

 <input type="submit" id="p1" class="subbut"
 onclick="makeRequest('p1');"
 value="f:=cos(x)/sin(x)*log(sin(x)^2/(cos(x)^2+sin(x)^2))" />
 <div id="ansp1"><div></div></div>

 <input type="submit" id="p2" class="subbut"
 onclick="handleFree(['p1','p2']);"
 value="g:=simplify f" />
 <div id="ansp2"><div></div></div>

```

If the result of [simplify](dbopsimplify.xhtml) is not satisfactory, specific transformations are available. For example, to rewrite  $g$  in terms of secants and cosecants instead of sines and cosines, issues:

```

 <input type="submit" id="p3" class="subbut"
 onclick="handleFree(['p1','p2','p3']);"
 value="h:=sin2csc cos2sec g" />
 <div id="ansp3"><div></div></div>

```

To apply the logarithm simplification rules to  $h$ , issue:

```

```

```

 <input type="submit" id="p4" class="subbut"
 onclick="handleFree(['p1','p2','p3','p4']);"
 value="h:=expandLog h" />
 <div id="ansp4"><div></div></div>

```

Since the square root of  $x^2$  is the absolute value of  $x$  and not  $x$  itself, algebraic radicals are not automatically simplified, but you can specifically request it by calling

```
rootSimp
```

```

 <input type="submit" id="p5" class="subbut"
 onclick="makeRequest('p5');"
 value="f1:=sqrt((x+1)^3)" />
 <div id="ansp5"><div></div></div>

 <input type="submit" id="p6" class="subbut"
 onclick="makeRequest('p6');"
 value="rootSimp f1" />
 <div id="ansp6"><div></div></div>

```

There are other transformations which are sometimes useful. Use the functions

```

complexElementary and
trigs to go back and forth between
the complex exponential and trigonometric forms of an elementary function.

```

```

 <input type="submit" id="p7" class="subbut"
 onclick="makeRequest('p7');"
 value="g1:=sin(x+cos x)" />
 <div id="ansp7"><div></div></div>

 <input type="submit" id="p8" class="subbut"
 onclick="handleFree(['p7','p8']);"
 value="g2:=complexElementary g1" />
 <div id="ansp8"><div></div></div>

 <input type="submit" id="p9" class="subbut"
 onclick="handleFree(['p7','p8','p9']);"
 value="trigs g2" />

```

```
<div id="ansp9"><div></div></div>
```

```

```

```

```

Similarly, the functions

[realElementary](dboprealelementary.xhtml) and

[htrigs](dbophtrigs.xhtml) convert hyperbolic functions in and out of their exponential form.

```

```

```

```

```
<input type="submit" id="p10" class="subbut"
```

```
 onclick="makeRequest('p10');"
```

```
 value="h1:=sinh(x+cosh x)" />
```

```
<div id="ansp10"><div></div></div>
```

```

```

```

```

```
<input type="submit" id="p11" class="subbut"
```

```
 onclick="handleFree(['p10','p11']);"
```

```
 value="h2:=realElementary h1" />
```

```
<div id="ansp11"><div></div></div>
```

```

```

```

```

```
<input type="submit" id="p12" class="subbut"
```

```
 onclick="handleFree(['p10','p11','p12']);"
```

```
 value="htrigs h2" />
```

```
<div id="ansp12"><div></div></div>
```

```

```

```

```

Axiom has other transformations, most of which are in the packages

[ElementaryFunctionStructurePackage](db.xhtml?ElementaryFunctionStructurePackage),

[TrigonometricManipulations](db.xhtml?TrigonometricManipulations),

[AlgebraicManipulations](db.xhtml?AlgebraicManipulations), and

[TranscendentalManipulations](db.xhtml?TranscendentalManipulations). If you need to apply a simplification

rule not built into the system you can use Axiom's

[pattern matcher](funpatternmatching.xhtml).

```

```

abstract datatype
 a programming language principle used in Axiom where a datatype is
 defined in two parts: (1) a <div class="gsyntax">public</div> part
 describing a set of exports, principally operations
 that apply to objects of that type, and (2) a
 <div class="gsyntax">private</div> part describing the implementation of
 the datatype usually in terms of a representation for
 objects of the type. Programs which create and otherwise manipulate objects
 of the type may only do so through its exports. The representation and
 other implementation information is specifically hidden.

abstraction
 described functionally or conceptually without regard to implementation

accuracy
 the degree of exactness of an approximation or measurement. In computer
 algebra systems, computations are typically carried out with complete
 accuracy using integers or rational numbers of indefinite size. Domain
 <div class="gtype">Float</div> provides a function
 <div class="gfunction">precision</div> from
 <div class="gtype">Float</div> to change the precision for floating point
 computations. Computations using <div class="gtype">DoubleFloat</div>
 have a fixed precision but uncertain accuracy.

add-chain
 a hierarchy formed by domain extensions. If domain
 <div class="gspad">A</div> extends domain <div class="gspad">B</div> and
 domain <div class="gspad">B</div> extends domain <div class="gspad">C</div>,
 then <div class="gspad">A</div> has <div class="gsyntax">add-chain</div>
 <div class="gspad">B</div>-<div class="gspad">C</div>.

aggregate
 a data structure designed to hold multiple values. Examples of aggregates
 are <div class="gtype">List</div>, <div class="gtype">Set</div>,
 <div class="gtype">Matrix</div> and <div class="gtype">Bits</div>.

AKCL
 Austin Kyoto Common LISP, a version of
 <div class="gspad">KCL</div> produced by
 William Schelter, Austin, Texas.

algorithm
 a step-by-step procedure for a solution of a problem; a program

```

```

ancestor
 (of a domain) a category which is a parent of the
 domain, or a parent of a
 parent and so on.

application
 <div class="gsyntax">(syntax)</div> an expression denoting "application"
 of a function to a set of argument parameters.
 Applications are written as a parameterized form.
 For example, the form <div class="gspad">f(x, y)</div> indicates the
 "application of the function <div class="gspad">f</div> to the tuple of
 arguments <div class="gspad">x</div> and <div class="gspad">y</div>".
 See also evaluation and
 invocation.

apply
 See application.

argument

 (actual argument) a value passed to a function at the time of a
 function call application; also called an
 <div class="gsyntax">actual parameter</div>.

 (formal argument) a variable used in the definition of a function
 to denote the actual argument passed when the function is called.

arity

 (function) the number of arguments.

 (operator or operation) corresponds to the arity of a function
 implementing the operator or operation.

assignment
 <div class="gsyntax">(syntax)</div> an expression of the form
 <div class="gspad">x := e</div>, meaning "assign the value of

```

`<div class="gspad">e</div>` to `<div class="gspad">x</div>`. After `<a href="#p19167">evaluation</a>`, the `<a href="#p52894">variable</a>` `<div class="gspad">x</div>` `<a href="#p39600">pointer</a>` to an object obtained by evaluating the expression `<div class="gspad">e</div>`. If `<div class="gspad">x</div>` has a `<a href="#p50664">type</a>` as a result of a previous `<a href="#p12903">declaration</a>`, the object assigned to `<div class="gspad">x</div>` must have that type. An interpreter must often `<a href="#p9572">coercion</a>` the value of `<div class="gspad">e</div>` to make that happen. For example, in the interpreter, `<div align="center" class="gspad">x : Float := 11</div>` first `<a href="#p12903">declaration</a>` `<div class="gspad">x</div>` to be a float. This declaration causes the interpreter to coerce 11 to 11.0 in order to assign a floating point value to `<div class="gspad">x</div>`.

`</li>`
`<li><a name="p4093" class="glabel"/><b>attribute</b>`  
 a name or functional form denoting `<div class="gsyntax">any</div>` useful computational property. For example, `<div class="gfunction">commutative(<div class="gspad">"*</div></div>` asserts that "`<div class="gfunction">"*</div>` is commutative". Also, `<div class="gfunction">finiteAggregate</div>` is used to assert that an aggregate has a finite number of immediate components.

`</li>`
`<li><a name="p4380" class="glabel"/><b>basis</b>`  
`<div class="gsyntax">(algebra)</div>` `<div class="gspad">S</div>` is a basis of a module `<div class="gspad">M</div>` over a `<a href="#p45405">ring</a>` if `<div class="gspad">S</div>` generates `<div class="gspad">M</div>`, and `<div class="gspad">S</div>` is linearly independent

`</li>`
`<li><a name="p4536" class="glabel"/><b>benefactor</b>`  
 (of a given domain) a domain or package that the given domain explicitly references (for example, calls functions from) in its implementation

`</li>`
`<li><a name="p4684" class="glabel"/><b>binary</b>`  
 operation or function with `<a href="#p3173">arity</a>` 2

`</li>`
`<li><a name="p4735" class="glabel"/><b>binding</b>`  
 the association of a variable with properties such as `<a href="#p52710">value</a>` and `<a href="#p50664">type</a>`. The top-level `<a href="#p19131">environment</a>` in the interpreter consists of bindings for all user variables and functions. Every `<a href="#p22911">function</a>` has an associated set of bindings, one for each formal `<a href="#p2885">argument</a>` and `<a href="#p32278">local variable</a>`.

`</li>`
`<li><a name="p5086" class="glabel"/><b>block</b>`

```

<div class="gsyntax">(syntax)</div> a control structure where
expressions are sequentially evaluation.

body
 a function body or loop body.

boolean
 objects denoted by the literals
 <div class="gspad">>true</div> and <div class="gspad">>false</div>;
 elements of domain <div class="gtype">Boolean</div>.
 See also <div class="gtype">Bits</div>.

built-in function
 a function in the standard Axiom library.
 Contrast user function.

cache

 (noun) a mechanism for immediate retrieval of previously computed data.
 For example, a function which does a lengthy computation might store
 its values in a hash table using argument as a
 key. The hash table then serves as a cache for the function (see also
 <div class="gcmd">)set function cache</div>). Also, when
 recurrence relations which depend upon
 <div class="gspad">n</div> previous values are compiled, the previous
 <div class="gspad">n</div> values are normally cached
 (use <div class="gcmd">)set functions recurrence</div> to change this).

 (verb) to save values in a cache.

capsule
 the part of the function body of a
 domain constructor that defines the functions
 implemented by the constructor.

case
 <div class="gsyntax">(syntax)</div> an operator used to
 conditionally evaluate code based on the branch of a
 Union. For example, if value
 <div class="gspad">u</div> is
 <div class="gspad">Union(Integer, "failed")</div>, the conditional
 expression <div class="gspad">if u case Integer then A else B</div>

```

```

 evaluate <div class="gspad">A</div> if <div class="gspad">u</div> is
 an integer and <div class="gspad">B</div> otherwise.

 Category
 the distinguished object denoting the type of a category; the class of
 all categories.

 category
 <div class="gsyntax">(basic concept)</div> second-order types which
 serve to define useful "classification worlds" for domains, such as
 algebraic constructs (e.g. groups, rings, fields), and data structures
 (e.g. homogeneous aggregates, collections, dictionaries). Examples of
 categories are <div class="gtype">Ring</div> ("the class of all
 rings") and <div class="gtype">Aggregate</div> ("the class of all
 aggregates"). The categories of a given world are arranged in a
 hierarchy (formally, a directed acyclic graph). Each category inherits
 the properties of all its ancestors. Thus, for example, the category
 of ordered rings (<div class="gtype">OrderedRing</div>) inherits the
 properties of the category of rings (<div class="gtype">Ring</div>)
 and those of the ordered sets
 (<div class="gtype">OrderedSet</div>). Categories provide a database of
 algebraic knowledge and ensure mathematical correctness, e.g. that
 "matrices of polynomials" is correct but "polynomials of hash tables"
 is not, that the multiply operation for "polynomials of continued
 fractions" is commutative, but that for "matrices of power series" is
 not. optionally provide "default definitions" for operations they
 export. Categories are defined in Axiom by functions called
 category constructors. Technically, a category
 designates a class of domains with common
 operations and attributes but
 usually with different functions and
 representations for its constituent
 objects. Categories are always defined using the
 Axiom library language (see also
 category extension).
 See also file <div class="gsyntax">catdef.spad</div>
 for definitions of basic algebraic categories in Axiom .

 category constructor
 a function that creates categories, described by an abstract
 datatype in the Axiom programming language. For example, the category
 constructor <div class="gtype">Module</div> is a function which takes
 a domain parameter <div class="gspad">R</div> and creates the category
 "modules over <div class="gspad">R</div>".

 category extension

```

created by a category definition, an expression usually of the form  
`<div class="gspad">A == B with ...</div>`. In English, this means  
 "category A is a `<div class="gspad">B</div>` with the new operations  
 and attributes as given by ... . See, for example, file  
`<div class="gsyntax">catdef.spad</div>` for a definitions of the algebra  
 categories in Axiom , `<div class="gsyntax">aggcat.spad</div>` for data  
 structure categories.

`</li>`

`<li><a name="p8996" class="glabel"/><b>category hierarchy</b>`  
 hierarchy formed by category extensions. The root category is  
`<div class="gtype">Object</div>`. A category can be defined as a  
`<a href="#p30459">Join</a>` of two or more categories so as to have  
 multiple `<a href="#p38095">parents</a>`. Categories may also have  
 parameterized so as to allow conditional inheritance.

`</li>`

`<li><a name="p9278" class="glabel"/><b>character</b>`  
`<ol>`  
`<li>`  
 an element of a character set, as represented by a keyboard key.  
`</li>`  
`<li>`  
 a component of a string. For example, the 0th element of the string  
`<div class="gspad">"hello there"</div>` is the character  
`<div class="gsyntax">h</div>`.  
`</li>`  
`</ol>`

`</li>`

`<li><a name="p9472" class="glabel"/><b>client</b>`  
 (of a given domain) any domain or package that explicitly calls  
 functions from the given domain

`</li>`

`<li><a name="p9572" class="glabel"/><b>coercion</b>`  
 an automatic transformation of an object of one  
`<a href="#p50664">type</a>` to an object of a similar or desired target  
 type. In the interpreter, coercions and  
`<a href="#p45044">retractions</a>` are done automatically by the  
 interpreter when a type mismatch occurs. Compare  
`<a href="#p12242">conversion</a>`.

`</li>`

`<li><a name="p9854" class="glabel"/><b>comment</b>`  
 textual remarks imbedded in code. Comments are preceded by a double  
 dash (`<div class="gsyntax">--</div>`). For Axiom library code,  
 stylized comments for on-line documentation are preceded by a two plus  
 signs (`<div class="gsyntax">++</div>`).

`</li>`

`<li><a name="p10064" class="glabel"/><b>Common LISP</b>`

A version of [LISP](#p31518) adopted as an informal standard by major users and suppliers of LISP

**compile-time**  
the time when category or domain constructors are compiled. Contrast [run-time](#p45818).

**compiler**  
a program that generates low-level code from a higher-level source language. Axiom has three compilers.

- A 

graphics compiler

 converts graphical formulas to a compiled subroutine so that points can be rapidly produced for graphics commands.
- An 

interpreter compiler

 optionally compiles [user functions](#p52526) when first [invocation](#p29675) (use 

set functions compile

 to turn this feature on).
- A 

library compiler

 compiles all constructors.

**computational object**  
In Axiom , domains are objects. This term is used to distinguish the objects which are members of domains rather than domains themselves.

**conditional**  
a [control structure](#p12001) of the form 

if A then B else C

; The [evaluation](#p19167) of 

A

 produces 

true

 or 

false

. If 

true

, 

B

 evaluates to produce a value; otherwise 

C

 evaluates to produce a value. When the value is not used, 

else C

 part can be omitted.

**constant**  

(syntax)

 a reserved word used in [signatures](#p46813) in Axiom programming language to signify

that mark an operation always returns the same value. For example, the signature `<div class="gspad">0: constant -> $</div>` in the source code of `<div class="gtype">AbelianMonoid</div>` tells the Axiom compiler that `<div class="gspad">0</div>` is a constant so that suitable optimizations might be performed.

</li>

<li><a name="p11642" class="glabel"/><b>constructor</b>  
a [function](#p22911) which creates a  
[category](#p6628), [domain](#p15041), or  
[package](#p36778).

</li>

<li><a name="p11755" class="glabel"/><b>continuation</b>  
when a line of a program is so long that it must be broken into several lines, then all but the first line are called  
`<div class="gsyntax">continuation lines</div>`. If such a line is given interactively, then each incomplete line must end with an underscore.

</li>

<li><a name="p12001" class="glabel"/><b>control structure</b>  
program structures which can specify a departure from normal sequential execution. Axiom has four kinds of control structures:  
[blocks](#p5086), [case](#p6220) statements,  
[conditionals](#p10941), and [loops](#p33121).

</li>

<li><a name="p12242" class="glabel"/><b>conversion</b>  
the transformation of an object on one [type](#p50664) to one of another type. Conversions performed automatically are called [coercions](#p9572). These happen when the interpreter has a type mismatch and a similar or declared target type is needed. In general, the user must use the infix operation  
`<div class="gspad">::</div>` to cause this transformation.

</li>

<li><a name="p12604" class="glabel"/><b>copying semantics</b>  
the programming language semantics used in Pascal but  
`<div class="gsyntax">not</div>` in Axiom . See also  
[pointer semantics](#p39949) for details.

</li>

<li><a name="p12740" class="glabel"/><b>data structure</b>  
a structure for storing data in the computer. Examples are  
[lists](#p31730) and [hash tables](#p25428).

</li>

<li><a name="p12850" class="glabel"/><b>datatype</b>  
equivalent to [domain](#p15041) in Axiom .

</li>

<li><a name="p12903" class="glabel"/><b>declaration</b>  
`<div class="gsyntax">(syntax)</div>` an expression of the form  
`<div class="gspad">x : T</div>` where `<div class="gspad">T</div>` is some

`<div class="gspad">type</div>`. A declaration forces all values  
`<a href="#p3322">assigned</a>` to `<div class="gspad">T</div>` to be of that  
 type. If a value is of a different type, the interpreter will try to  
`<a href="#p9572">coerce</a>` the value to type  
`<div class="gspad">T</div>`. Declarations are necessary in case of  
 ambiguity or when a user wants to introduce an an  
`<a href="#p20259">unexposed</a>` domain.  
`</li>`  
`<li><a name="p13351" class="glabel"/><b>default definition</b>`  
 a function defined by a `<a href="#p6628">category</a>`. Such  
 definitions appear category definitions of the form  
`<div class="gspad">C: Category == T add I</div>` in an optional  
 implementation part `<div class="gspad">I</div>` to the right of the  
 keyword `<div class="gspad">add</div>`.  
`</li>`  
`<li><a name="p13571" class="glabel"/><b>default package</b>`  
 a optional `<a href="#p36778">package</a>` of  
`<a href="#p22911">functions</a>` associated with a category. Such  
 functions are necessarily defined in terms over other functions  
 exported by the category.  
`</li>`  
`<li><a name="p13754" class="glabel"/><b>definition</b>`  
`<div class="gsyntax">(syntax)</div>`  
`<ol>`  
`<li>`  
 An expression of the form  
`<div class="gspad">f(a) == b</div>` defining function  
`<div class="gspad">f</div>` with `<a href="#p21594">formal arguments</a>`  
`<div class="gspad">a</div>` and `<a href="#p5198">body</a>`  
`<div class="gspad">b</div>`; equivalent to the statement  
`<div class="gspad">f == (a) +-> b</div>`.  
`</li>`  
`<li>`  
 An expression of the form  
`<div class="gspad">a == b</div>` where `<div class="gspad">a</div>` is a  
`<a href="#p49347">symbol</a>`, equivalent to  
`<div class="gspad">a() == b</div>`.  
 See also `<a href="#p33585">macro</a>` where a similar  
 substitution is done at `<a href="#p38242">parse</a>` time.  
`</li>`  
`</ol>`  
`</li>`  
`<li><a name="p14178" class="glabel"/><b>delimiter</b>`  
 a `<a href="#p9278">character</a>` which marks the beginning or end of  
 some syntactically correct unit in the language, e.g. " for strings,  
 blanks for identifiers.

```

destructive operation
 An operation which changes a component or structure of a value. In
 Axiom , all destructive operations have names which end with an
 exclamation mark (<div class="gsyntax">!</div>). For example, domain
 <div class="gtype">List</div> has two operations to reverse the
 elements of a list, one named <div class="gfunction">reverse</div>
 from <div class="gtype">List</div> which returns a copy of the
 original list with the elements reversed, another named
 <div class="gfunction">reverse!</div> from <div class="gtype">List</div>
 which reverses the elements <div class="gsyntax">in place</div> thus
 destructively changing the original list.

documentation

 on-line or hard copy descriptions of Axiom;

 text in library code preceded by
 <div class="gsyntax">++</div> comments as opposed to general comments
 preceded by <div class="gsyntax">--</div>.

domain
 <div class="gsyntax">(basic concept)</div> a domain corresponds to
 the usual notion of abstract datatypes: that of a set of values and a
 set of "exported operations" for the creation and manipulation of
 these values. Datatypes are parameterized, dynamically constructed,
 and can combine with others in any meaningful way, e.g. "lists of
 floats" (<div class="gtype">List Float</div>), "fractions of
 polynomials with integer coefficients"
 (<div class="gtype">Fraction Polynomial Integer</div>),
 "matrices of infinite streams of cardinal numbers"
 (<div class="gtype">Matrix Stream CardinalNumber</div>). The term
 <div class="gsyntax">domain</div> is actually abbreviates
 <div class="gsyntax">domain of computation</div>. Technically, a domain
 denotes a class of objects, a class of
 operations for creating and other manipulating
 these objects, and a class of attributes
 describing computationally useful properties. Domains also provide
 functions for each operation often in terms of some
 representation for the objects. A domain itself
 is an object created by a
 function called a domain

```

```

 constructor.

 domain constructor
 a function that creates domains, described by an abstract datatype in
 the Axiom programming language. Simple domains like
 <div class="gtype">Integer</div> and <div class="gtype">Boolean</div> are
 created by domain constructors with no arguments. Most domain
 constructors take one or more parameters, one usually denoting an
 underlying domain. For example, the domain
 <div class="gtype">Matrix(R)</div> denotes "matrices over
 <div class="gspad">R</div>. Domains <div class="gsyntax">Mapping</div>,
 <div class="gsyntax">Record</div>, and
 <div class="gsyntax">Union</div> are primitive domains. All other domains
 are written in the Axiom programming language and can be modified by
 users with access to the library source code.

 domain extension
 a domain constructor <div class="gspad">A</div> is said to
 <div class="gsyntax">extend</div> a domain constructor
 <div class="gspad">B</div> if <div class="gspad">A</div>
 <div class="gspad">'s</div> definition has the form
 <div class="gspad">A == B add ...</div>.
 This intuitively means "functions not defined by <div
 class="gspad">A</div> are assumed to come from
 <div class="gspad">B</div>". Successive domain extensions form
 add-chains affecting the the
 search order for functions not implemented directly
 by the domain during dynamic lookup.

 dot notation
 using an infix dot (<div class="gsyntax">.</div>) for function
 application. If <div class="gspad">u</div> is the list
 <div class="gspad">[7, 4, -11]</div> then both
 <div class="gspad">u(2)</div> and <div class="gspad">u.2</div> return
 4. Dot notation nests to left. Thus <div class="gspad">f . g . h</div>
 is equivalent to <div class="gspad">(f . g) . h</div>.

 dynamic
 that which is done at run-time as opposed to
 compile-time. For example, the interpreter will
 build the domain "matrices over integers" dynamically in response to
 user input. However, the compilation of all functions for matrices and
 integers is done during compile-time. Contrast
 static.

 dynamic lookup

```

In Axiom , a [domain](#p17507) may or may not explicitly provide [function](#p22911) definitions for all of its exported [operations](#p36041). These definitions may instead come from domains in the [add-chain](#p1794) or from [default packages](#p13571). When a [function call](#p2400) is made for an operation in the domain, up to five steps are carried out.

- 

If the domain itself implements a function for the operation, that function is returned.

- 

Each of the domains in the [add-chain](#p1794) are searched for one which implements the function; if found, the function is returned.

- 

Each of the [default packages](#p13571) for the domain are searched in order of the [lineage](#p30933). If any of the default packages implements the function, the first one found is returned.

- 

Each of the [default packages](#p13571) for each of the domains in the [add-chain](#p1794) are searched in the order of their [lineage](#p30933). If any of the default packages implements the function, the first one found is returned.

- If all of the above steps fail, an error message is reported.
- empty**

the unique value of objects with type [Void](#p19071).

- environment**

a set of [bindings](#p4735).

- evaluation**

a systematic process which transforms an

[expression](#p20659) into an object called the

[value](#p52710) of the expression. Evaluation may produce

[side effects](#p46699).

- exit**

[\(reserved word\)](#p19348) an

```

operator which forces an exit from the current
block. For example, the block
<div class="gspad">(a := 1; if i > 0 then exit a; a := 2)</div> will
prematurely exit at the second statement with value 1 if the value of
<div class="gspad">i</div> is greater than 0. See
<div class="gspad">=</div> for an alternate syntax.

explicit export

 (of a domain <div class="gspad">D</div>) any
 attribute, operation, or
 category explicitly mentioned in the
 type specification part <div class="gspad">T</div>
 for the domain constructor definition <div class="gspad">D: T == I</div>

 (of a category <div class="gspad">C</div>) any
 attribute, operation, or
 category explicitly mentioned in the
 type specification part <div class="gspad">T</div>
 for the domain constructor definition
 <div class="gspad">C: Category == T</div>

export
 explicit export or implicit
 export of a domain or category

expose
 some constructors are <div class="gsyntax">exposed</div>, others
 <div class="gsyntax">unexposed</div>. Exposed domains and packages
 are recognized by the interpreter. Use
 <div class="gcmd">>set expose</div>
 to control change what is exposed. To see both exposed
 and unexposed constructors, use the browser with give the system
 command <div class="gcmd">>set hyperdoc browse exposure
 on</div>. Unexposed constructors will now appear prefixed by star
 (<div class="gspad">*</div>).

expression

 any syntactically correct program fragment.

 an element of domain <div class="gtype">Expression</div>

```

```

extend
 see category extension or domain
 extension

field
 <div class="gsyntax">(algebra)</div> a domain
 which is ring where every non-zero element is
 invertible and where <div class="gspad"> $xy=yx$ </div>; a member of
 category <div class="gtype">Field</div>. For a complete list of
 fields, click on <div class="gsyntax">Domains</div> under
 <div class="gsyntax">Cross Reference</div> for
 <div class="gtype">Field</div>.

file
 a program or collection of data stored on disk, tape or other medium.

float
 a floating-point number with user-specified precision; an element of
 domain <div class="gtype">Float</div>. Floats are
 literals which are written two ways: without an
 exponent (e.g. <div class="gspad">3.1416</div>), or with an exponent
 (e.g. <div class="gspad">3.12E-12</div>). Use function
 precision to change the precision of the mantissage
 (20 digits by default). See also small float.

formal parameter
 (of a function) an identifier bound to the value
 of an actual argument on
 invocation. In the function definition
 <div class="gspad"> $f(x, y) == u$ </div>, for example,
 <div class="gspad"> x </div> and <div class="gspad"> y </div> are the formal
 parameter.

frame
 the basic unit of an interactive session; each frame has its own
 step number, environment, and
 history. In one interactive session, users can
 create and drop frames, and have several active frames simultaneously.

free
 <div class="gsyntax">(syntax)</div> A keyword used in user-defined
 functions to declare that a variable is a
 free variable of that function.

```

For example, the statement

```
<div class="gspad">free x</div> declares the variable
<div class="gspad">x</div> within the body of a function
<div class="gspad">f</div> to be a free variable in
<div class="gspad">f</div>. Without such a declaration, any variable
<div class="gspad">x</div> which appears on the left hand side of an
assignment is regarded as a local variable of
that function. If the intention of the assignment is to give an value
to a global variable <div class="gspad">x</div>,
the body of that function must contain the statement
<div class="gspad">free x</div>.
```

</li>

<li><a name="p22739" class="glabel"/><b>free variable</b>

(of a function) a variable which appears in a body of a function but
is not <a href="#p4735">bound</a> by that function. See
<a href="#p32278">local variable</a> by default.

</li>

<li><a name="p22911" class="glabel"/><b>function</b>

implementation of <a href="#p36041">operation</a>; it takes zero or
more <a href="#p2885">argument</a> parameters and produces zero or
more values. Functions are objects which can be passed as parameters
to functions and can be returned as values of functions. Functions can
also create other functions (see also

```
<div class="gtype">InputForm</div>). See also
```

```
application and
```

```
invocation. The terms
```

```
<div class="gsyntax">operation</div> and
```

```
<div class="gsyntax">function</div> are distinct notions in Axiom . An
operation is an abstraction of a function, described by declaring a
signature. A function is created by providing an
implementation of that operation by some piece of Axiom code. Consider
the example of defining a user-function <div class="gspad">fact</div>
to compute the <div class="gfunction">factorial</div> of a nonnegative
integer. The Axiom statement
```

```
<div class="gspad">fact: Integer -> Integer</div>
```

describes the operation, whereas the statement

```
<div class="gspad">fact(n) = reduce(*, [1..n])</div> defines the
```

```
functions. See also generic function.
```

</li>

<li><a name="p23911" class="glabel"/><b>function body</b>

the part of a <a href="#p22911">function</a>

```
<div class="gspad">'s</div> definition which is evaluated when the function
is called at run-time; the part of the function
definition to the right of the <div class="gspad">==</div>.
```

</li>

<li><a name="p2400" class="glabel"/><b>function call</b>

`<div class="gsyntax">(syntax)</div>` an expression denoting  
 "application" of a function to a set of `<a href="#p2885">argument</a>`  
 parameters. Applications are written as a  
`<a href="#p38004">parameterized form</a>`. For example, the form  
`<div class="gspad">f(x, y)</div>` indicates the "application of the function  
`<div class="gspad">f</div>` to the tuple of arguments  
`<div class="gspad">x</div>` and `<div class="gspad">y</div>`. See also  
`<a href="#p19167">evaluation</a>` and `<a href="#p29675">invocation</a>`.  
`</li>`  
`<li><a name="p24123" class="glabel"/><b>garbage collection</b>`  
 a system function that automatically recycles memory cells from the  
`<a href="#p25771">heap</a>`. Axiom is built upon  
`<a href="#p10064">Common LISP</a>` which provides this facility.  
`</li>`  
`<li><a name="p24294" class="glabel"/><b>garbage collector</b>`  
 a mechanism for reclaiming storage in the `<a href="#p25771">heap</a>`.  
`</li>`  
`<li><a name="p24359" class="glabel"/><b>Gaussian</b>`  
 a complex-valued expression, e.g. one with both a real and imaginary  
 part; a member of a `<div class="gtype">Complex</div>` domain.  
`</li>`  
`<li><a name="p24495" class="glabel"/><b>generic function</b>`  
 the use of one function to operate on objects of different types; One  
 might regard Axiom as supporting generic  
`<a href="#p36041">operations</a>` but not generic functions. One operation  
`<div class="gspad">+: (D, D) -> D</div>` exists for adding elements in  
 a ring; each ring however provides its own type-specific function for  
 implementing this operation.  
`</li>`  
`<li><a name="p24833" class="glabel"/><b>global variable</b>`  
 A variable which can be referenced freely by functions. In Axiom ,  
 all top-level user-defined variables defined during an interactive  
 user session are global variables. Axiom does not allow `<div`  
`class="gsyntax">fluid variables</div>`, that is, variables  
`<a href="#p4735">bound</a>` by functions which can be referenced by  
 functions those functions call.  
`</li>`  
`<li><a name="p25189" class="glabel"/><b>Groebner basis</b>`  
`<div class="gsyntax">(algebra)</div>` a special basis for a  
 polynomial ideal that allows a simple test for membership. It is  
 useful in solving systems of polynomial equations.  
`</li>`  
`<li><a name="p25348" class="glabel"/><b>group</b>`  
`<div class="gsyntax">(algebra)</div>` a `<a href="#p34266">monoid</a>`  
 where every element has a multiplicative inverse.  
`</li>`

```

hash table
 A data structure that efficiency maps a given object to another. A
 hash table consists of a set of <div class="gsyntax">entries</div>,
 each of which associates a <div class="gsyntax">key</div> with a
 <div class="gsyntax">value</div>. Finding the object stored under a key
 can be very fast even if there are a large number of entries since
 keys are <div class="gsyntax">hashed</div> into numerical codes for
 fast lookup.

heap
 an area of storage used by data in programs. For example, AXIOM will
 use the heap to hold the partial results of symbolic
 computations. When cancellations occur, these results remain in the
 heap until garbage collected.

history
 a mechanism which records the results for an interactive
 computation. Using the history facility, users can save computations,
 review previous steps of a computation, and restore a previous
 interactive session at some later time. For details, issue the system
 command <div class="gsyntax">history ?</div> to the interpreter. See
 also frame.

ideal
 <div class="gsyntax">(algebra)</div> a subset of a ring that is
 closed under addition and multiplication by arbitrary ring elements,
 i.e. it<div class="gspad">'s</div> a module over the ring.

identifier
 <div class="gsyntax">(syntax)</div> an Axiom name; a
 literal of type <div class="gtype">Symbol</div>. An
 identifier begins with an alphabetical character or % and may be
 followed by alphabetic characters, digits, ? or !. Certain
 distinguished reserved words are not allowed as
 identifiers but have special meaning in the Axiom .

immutable
 an object is immutable if it cannot be changed by an
 operation; not a mutable
 object. Algebraic objects generally immutable: changing an
 algebraic expression involves copying parts of the original
 object. One exception is a matrix object of type
 <div class="gtype">Matrix</div>. Examples of mutable objects are data
 structures such as those of type <div class="gtype">List</div>. See
 also pointer semantics.

```

```

implicit export
 (of a domain or category) any attribute or
 operation which is either an explicit export or
 else an explicit export of some category which an explicit category
 export extends.

index

 a variable that counts the number of times a
 loop is repeated.

 the "address" of an element in a data structure (see also category
 <div class="gtype">LinearAggregate</div>).

infix
 <div class="gsyntax">(syntax)</div> an
 operator placed between two
 operands; also called a
 <div class="gsyntax">binary operator</div>, e.g.
 <div class="gspad">a + b</div>. An infix operator may also be used as a
 prefix, e.g. <div class="gspad">+(a, b)</div> is
 also permissible in the Axiom language. Infix operators have a
 relative precedence.

input area
 a rectangular area on a screen into which users can enter text.

instantiate
 to build a category, domain,
 or package at run-time

integer
 a literal object of domain
 <div class="gtype">Integer</div>, the class of integers with an unbounded
 number of digits. Integer literals consist of one or more consecutive
 digits (0-9) with no embedded blanks. Underscores can be used to
 separate digits in long integers if desirable.

interactive
 a system where the user interacts with the computer step-by-step

interpreter

```

the subsystem of Axiom responsible for handling user input during an interactive session. The following somewhat simplified description of the typical action of the interpreter. The interpreter parses the user `<div class="gspad">'s</div>` input expression to create an expression tree then does a bottom-up traversal of the tree. Each subtree encountered which is not a value consists of a root node denoting an operation name and one or more leaf nodes denoting `<a href="#p35946">operands</a>`. The interpreter resolves type mismatches and uses type-inferencing and a library database to determine appropriate types of the operands and the result, and an operation to be performed. The interpreter then builds a domain to perform the indicated operation, then invokes a function from the domain to compute a value. The subtree is then replaced by that value and the process continues. Once the entire tree has been processed, the value replacing the top node of the tree is displayed back to the user as the value of the expression.

`</li>`

`<li><a name="p29675" class="glabel"/><b>invocation</b>`

(of a function) the run-time process involved in `<a href="#p19167">evaluating</a>` a `<a href="#p22911">function</a>` `<a href="#p2473">application</a>`. This process has two steps. First, a local `<a href="#p19131">environment</a>` is created where `<a href="#p21594">formal arguments</a>` are locally `<a href="#p4735">bound</a>` by `<a href="#p3322">assignment</a>` to their respective actual `<a href="#p2885">argument</a>`. Second, the `<a href="#p23911">function body</a>` is evaluated in that local environment. The evaluation of a function is terminated either by completely evaluating the function body or by the evaluation of a `<div class="gfunction">return</div>` expression.

`</li>`

`<li><a name="p30286" class="glabel"/><b>iteration</b>`

repeated evaluation of an expression or a sequence of expressions. Iterations use the reserved words `<div class="gfunction">for</div>`, `<div class="gfunction">while</div>`, and `<div class="gfunction">repeat</div>`.

`</li>`

`<li><a name="p30459" class="glabel"/><b>Join</b>`

a primitive Axiom function taking two or more categories as arguments and producing a category containing all of the operations and attributes from the respective categories.

`</li>`

`<li><a name="p30645" class="glabel"/><b>KCL</b>`

Kyoto Common LISP, a version of `<a href="#p10064">Common LISP</a>` which features compilation of the compilation of LISP into the `<div class="gspad">C</div>` Programming Language

`</li>`

```

library
 In Axiom , a coollection of compiled modules resrepresenting the a
 category or domain
 constructor.

lineage
 the sequence of default packages for a given
 domain to be searched during
 dynamic lookup.
 This sequence is computed first by ordering the category
 ancestors of the domain according to their <div
 class="gsyntax">level number</div>, an integer equal to to the
 minimum distance of the domain from the category. Parents have level
 1, parents of parents have level 2, and so on. Among categories with
 equal level numbers, ones which appear in the left-most branches of
 <div class="gsyntax">Join</div><div class="gspad">s</div> in the
 source code come first. See also dynamic lookup.

LISP
 acronymn for List Processing Language, a language designed for the
 manipulation of nonnumerical data. The Axiom library is translated
 into LISP then compiled into machine code by an underlying LISP.

list
 an object of a <div class="gtype">List</div> domain.

literal
 an object with a special syntax in the language. In Axiom , there are
 five types of literals: booleans,
 integers, floats,
 strings, and symbols.

local
 <div class="gsyntax">(syntax)</div> A keyword used in user-defined
 functions to declare that a variable is a
 local variable of that function.
 Because of default assumptions on
 variables, such a declaration is not necessary but is available to the
 user for clarity when appropriate.

local variable
 (of a function) a variable bound by that
 function and such that its binding is invisible to any function that
 function calls. Also called a <div class="gsyntax">lexical</div>
 variable. By default in the interpreter:

```

```

 any variable <div class="gspad">x</div> which appears on the left hand
 side of an assignment is regarded a local variable of that
 function. If the intention of an assignment is to change the value of
 a global variable <div class="gspad">x</div>,
 the body of the function must then contain the statement
 <div class="gspad">free x</div>.

 any other variable is regarded as a free variable.

 An optional declaration <div class="gspad">local x</div> is available
 to explicitly declare a variable to be a local variable. All
 formal parameters to the function can be regarded
 as local variables to the function.

loop

 an expression containing a <div class="gfunction">repeat</div>

 a collection expression having a <div class="gfunction">for</div> or a
 <div class="gfunction">while</div>, e.g.
 <div class="gspad">[f(i) for i in S]</div>.

loop body
 the part of a loop following the <div class="gfunction">repeat</div>
 that tells what to do each iteration. For example, the body of the
 loop <div class="gspad">for x in S repeat B</div> is
 <div class="gspad">B</div>. For a collection expression, the body of the
 loop precedes the initial <div class="gfunction">for</div> or
 <div class="gfunction">while</div>.

macro

 <div class="gsyntax">(syntax)</div> An expression of the form
 <div class="gspad">macro a == b</div> where <div class="gspad">a</div> is a
 symbol causes <div class="gspad">a</div> to be
 textually replaced by the expression <div class="gspad">b</div> at
 parse time.

```

```

 An expression of the form <div class="gspad">macro f(a) == b</div>
 defines a parameterized macro expansion for a parameterized form
 <div class="gspad">f</div> This macro causes a form
 <div class="gspad">f</div>(<div class="gspad">x</div>) to be textually
 replaced by the expression <div class="gspad">c</div> at parse time,
 where <div class="gspad">c</div> is the expression obtained by
 replacing <div class="gspad">a</div> by <div class="gspad">x</div>
 everywhere in <div class="gspad">b</div>. See also
 definition where a similar substitution is done
 during evaluation.

mode
 a type expression containing a question-mark
 (<div class="gsyntax">?</div>). For example, the mode
 <div class="gsyntax">P ?</div> designates <div class="gsyntax">the class
 of all polynomials over an arbitrary ring</div>.

monoid
 is a set with a single, associative operation and an identity element

mutable
 objects which contain pointers to other objects
 and which have operations defined on them which alter these
 pointers. Contrast immutable. Axiom uses
 pointer semantics as does
 LISP in contrast with many other languages such as
 Pascal which use copying semantics. See
 pointer semantics for details.

name

 a symbol denoting a variable,
 i.e. the variable <div class="gspad">x</div>.

 a symbol denoting an
 operation, i.e. the operation
 <div class="gspad">divide: (Integer, Integer) -> Integer</div>.

```

```

>nullary
 a function with no arguments,
 e.g. <div class="gfunction">characteristic</div>.

>nullary
 operation or function with arity 0

Object
 a category with no operations or attributes, from which most categories
 in Axiom are category extensions.

object
 a data entity created or manipulated by programs. Elements of
 domains, functions, and domains themselves are objects. Whereas
 categories are created by functions, they cannot be dynamically
 manipulated in the current system and are thus not considered as
 objects. The most basic objects are literals;
 all other objects must be created
 functions. Objects can refer to other objects using
 pointers. Axiom language uses
 pointer semantics when dealing with
 mutable objects.

object code
 code which can be directly executed by hardware; also known as
 <div class="gsyntax">machine language</div>.

operand
 an argument of an operator (regarding an
 operator as a function).

operation
 an abstraction of a function, described by a
 signature. For example,
 <div align="center" class="gspad">
 fact: NonNegativeInteger -> NonNegativeInteger
 </div>
 describes an operation for "the factorial of a (non-negative) integer".

operator
 special reserved words in the language such as
 <div class="gfunction">+</div> and <div class="gfunction">*</div>;
 operators can be either prefix or
 infix and have a relative
 precedence.

```

- <li><a name="p36465" glabel="class"/><b>overloading</b>  
the use of the same name to denote distinct functions; a function is identified by a <a href="#p46813">signature</a> identifying its name, the number and types of its arguments, and its return types. If two functions can have identical signatures, a <a href="#p37520">package call</a> must be made to distinguish the two.  
</li>
- <li><a name="p36778" class="glabel"/><b>package</b>  
a domain whose exported operations depend solely on the parameters and other explicit domains, e.g. a package for solving systems of equations of polynomials over any field, e.g. floats, rational numbers, complex rational functions, or power series. Facilities for integration, differential equations, solution of linear or polynomial equations, and group theory are provided by "packages". Technically, a package is a domain which has no <a href="#p46813">signature</a> containing the symbol \$. While domains intuitively provide computational objects you can compute with, packages intuitively provide functions (<a href="#p41450">polymorphic</a> functions) which will work over a variety of datatypes.  
</li>
- <li><a name="p37520" class="glabel"/><b>package call</b>  
<div class="gsyntax">(syntax)</div> an expression of the form  
<div class="gspad">e \$ D</div> where <div class="gspad">e</div> is an <a href="#p2473">application</a> and <div class="gspad">D</div> denotes some <a href="#p36778">package</a> (or <a href="#p17507">domain</a>).  
</li>
- <li><a name="p37696" class="glabel"/><b>package call</b>  
<div class="gsyntax">(syntax)</div> an expression of the form  
<div class="gspad">f(x, y)\$D</div> used to identify that the function <div class="gspad">f</div> is to be one from <div class="gspad">D</div>.  
</li>
- <li><a name="p37833" class="glabel"/><b>package constructor</b>  
same as <a href="#p16173">domain constructor</a>.  
</li>
- <li><a name="p37878" class="glabel"/><b>parameter</b>  
see <a href="#p2885">argument</a>  
</li>
- <li><a name="p37908" class="glabel"/><b>parameterized datatype</b>  
a domain that is built on another, for example, polynomials with integer coefficients.  
</li>
- <li><a name="p38004" class="glabel"/><b>parameterized form</b>  
a expression of the form <div class="gspad">f(x, y)</div>, an <a href="#p2473">application</a> of a function.  
</li>
- <li><a name="p38095" class="glabel"/><b>parent</b>

(of a domain) a category which is explicitly declared in the source code definition for the domain to be an [export](#p20171) of the domain.

**parse**

- (verb) to produce an internal representation of a user input string; the resultant internal representation is then "interpreted" by Axiom to perform some indicated action.
- the transformation of a user input string representing a valid Axiom expression into an internal representation as a tree-structure.

**partially ordered set**  
a set with a reflexive, transitive and antisymmetric [binary](#p4684) operation.

**pattern**  
The left hand side of a rewrite rule is called a pattern. Rewrite rules can be used to perform pattern matching, usually for simplification. The right hand side of a rule is called the [substitution](#p49000).

**pattern match**

- (on expressions) Given a expression called a "subject" 

u

, the attempt to rewrite 

u

 using a set of "rewrite rules". Each rule has the form 

A == B

 where 

A

 indicates a expression called a "pattern" and 

B

 denotes a "replacement". The meaning of this rule is "replace 

A

 by 

B

". If a given pattern 

A

 matches a subexpression of 

u

, that subexpression is replaced by 

B

. Once rewritten, pattern matching continues until no further changes occur.

(on strings) the attempt to match a string indicating a "pattern" to another string called a "subject", for example, for the purpose of identifying a list of names. In a browser, users may enter

[search strings](#p46294) for the purpose of identifying constructors, operations, and attributes.

**pattern variable**  
 In a rule a symbol which is not a recognized function acts as a pattern variable and is free to match any subexpression.

**pile**  
 alternate syntax for a block, using indentation and column alignment (see also [block](#p5086)).

**pointer**  
 a reference implemented by a link directed from one object to another in the computer memory. An object is said to `<div class="gsyntax">refer</div>` to another if it has a pointer to that other object. Objects can also refer to themselves (cyclic references are legal). Also more than one object can refer to the same object. See also [pointer semantics](#p39949).

**pointer semantics**  
 the programming language semantics used in languages such as LISP which allow objects to be [mutable](#p34398). Consider the following sequence of Axiom statements:

```

 <div class="gspad">x : Vector Integer := [1, 4, 7]</div>

 <div class="gspad">y := x</div>

 <div class="gspad">swap!(x, 2, 3)</div>

```

The function `<div class="gfunction">swap!</div>` from `<div class="gtype">Vector</div>` is used to interchange the 2nd and 3rd value in the list `<div class="gspad">x</div>` producing the value `<div class="gspad">[1, 7, 4]</div>`. What value does `<div class="gspad">y</div>` have after evaluation of the third statement? The answer is different in Axiom than it is in a language with [copying semantics](#p12604). In Axiom, first the vector `[1, 2, 3]` is created and the variable `<div class="gspad">x</div>` set to [point](#p39600) to this object. Let `<div class="gspad">'s</div>` call this object `<div class="gspad">V</div>`. Now `<div class="gspad">V</div>` refers to its [immutable](#p26892) components 1, 2, and 3. Next, the variable `<div class="gspad">y</div>` is made to point to

`<div class="gspad">V</div>` just as `<div class="gspad">x</div>` does. Now the third statement interchanges the last 2 elements of `<div class="gspad">V</div>` (the `<div class="gsyntax">!` at the end of the name `<div class="gfunction">swap!` from `<div class="gtype">Vector</div>` tells you that this operation is destructive, that is, it changes the elements `<div class="gsyntax">in place</div>`). Both `<div class="gspad">x</div>` and `<div class="gspad">y</div>` perceive this change to `<div class="gspad">V</div>`. Thus both `<div class="gspad">x</div>` and `<div class="gspad">y</div>` then have the value `<div class="gspad">[1, 7, 4]</div>`. In Pascal, the second statement causes a copy of `<div class="gspad">V</div>` to be stored under `<div class="gspad">y</div>`. Thus the change to `<div class="gspad">V</div>` made by the third statement does not affect `<div class="gspad">y</div>`.

**polymorphic**  
 a `<a href="#p22911">function</a>` parameterized by one or more `<a href="#p17507">domains</a>`; a `<a href="#p2267">algorithm</a>` defined `<a href="#p6628">categorically</a>`. Every function defined in a domain or package constructor with a domain-valued parameter is polymorphic. For example, the same matrix `<div class="gfunction">*</div>` function is used to multiply "matrices over integers" as "matrices over matrices over integers"

**postfix**  
 an `<a href="#p36278">operator</a>` that follows its single `<a href="#p35946">operand</a>`. Postfix operators are not available in Axiom.

**precedence**  
`<div class="gsyntax">(syntax)</div>` refers to the so-called `<div class="gsyntax">binding power</div>` of an operator. For example, `<div class="gspad">*</div>` has higher binding power than `<div class="gspad">+</div>` so that the expression `<div class="gspad">a + b * c</div>` is equivalent to `<div class="gspad">a + (b * c)</div>`.

**precision**  
 the number of digits in the specification of a number, e.g. as set by `<div class="gfunction">precision</div>` from `<div class="gtype">Float</div>`.

**predicate**  

- a Boolean valued function, e.g.

```

 <div class="gspad">odd: Integer -> Boolean</div>.

 an Boolean valued expression

prefix
 <div class="gsyntax">(syntax)</div> an
 operator such as <div class="gspad">-</div> and
 <div class="gspad">not</div> that is written
 <div class="gsyntax">before</div> its single
 operand. Every function of one argument can be used
 as a prefix operator. For example, all of the following have
 equivalent meaning in Axiom : <div class="gspad">f(x)</div>,
 <div class="gspad">f x</div>, and <div class="gspad">f.x</div>. See also
 dot notation.

quote
 the prefix operator
 <div class="gfunction">'</div> meaning <div class="gsyntax">do not
 evaluate</div>.

Record
 (basic domain constructor) a domain constructor used to create a
 inhomogeneous aggregate composed of pairs of "selectors" and
 values. A Record domain is written in the form
 <div class="gspad">Record(a1:D1, ..., an:Dn)</div>
 (<div class="gspad">n</div> > 0) where <div class="gspad">a1</div>, ...,
 <div class="gspad">an</div> are identifiers called the
 <div class="gsyntax">selectors</div> of the record, and
 <div class="gspad">D1</div>, ..., <div class="gspad">Dn</div> are domains
 indicating the type of the component stored under selector
 <div class="gspad">an</div>.

recurrence relation
 A relation which can be expressed as a function
 <div class="gspad">f</div> with some argument <div class="gspad">n</div>
 which depends on the value of <div class="gspad">f</div> at
 <div class="gspad">k</div> previous values. In many cases, Axiom will
 rewrite a recurrence relation on compilation so as to
 cache its previous <div class="gspad">k</div> values
 and therefore make the computation significantly more efficient.

recursion
 use of a self-reference within the body of a function. Indirect
 recursion is when a function uses a function below it in the call

```

```

 chain.

 recursive

 A function that calls itself, either directly or indirectly through
 another function.

 self-referential. See also recursive.

 reference
 see pointer

 Rep
 a special identifier used as local variable of
 a domain constructor body to denote the representation domain for
 objects of a domain.

 representation
 a domain providing a data structure for
 elements of a domain; generally denoted by the special identifier
 Rep in the Axiom programming language. As domains
 are abstract datatypes, this representation is not
 available to users of the domain, only to functions defined in the
 function body for a domain constructor. Any domain
 can be used as a representation.

 reserved word
 a special sequence of non-blank characters with special meaning in
 the Axiom language. Examples of reserved words are names such as
 <div class="gfunction">for</div>, <div class="gfunction">if</div>, and
 <div class="gfunction">free</div>, operator names such as
 <div class="gfunction">+</div> and <div class="gspad">mod</div>, special
 character strings such as <div class="gspad">==</div> and
 <div class="gspad">:=</div>.

 retraction
 to move an object in a parameterized domain back to the underlying
 domain, for example to move the object <div class="gspad">7</div> from
 a "fraction of integers"
 (domain <div class="gtype">Fraction Integer</div>) to
 "the integers" (domain <div class="gtype">Integer</div>).

 return
 when leaving a function, the value of the expression following

```

```

 <div class="gfunction">return</div> becomes the value of the function.

 ring
 a set with a commutative addition, associative multiplication, a unit
 element, and multiplication distributes over addition and subtraction.

 rule
 <div class="gsyntax">(syntax)</div> 1. An expression of the form
 <div class="gspad">rule A == B</div> indicating a "rewrite
 rule". 2. An expression of the form
 <div class="gspad">rule(R1;...;Rn)</div>
 indicating a set of "rewrite rules"
 <div class="gspad">R1</div>, ..., <div class="gspad">Rn</div>. See
 pattern matching for details.

 run-time
 the time of doing a computation. Contrast
 compile-time. rather than prior to it;
 dynamic as opposed to
 static. For example, the decision of the interpreter
 to build a structure such as "matrices with power series entries" in
 response to user input is made at run-time.

 run-time check
 an error-checking which can be done only when the program receives
 user input; for example, confirming that a value is in the proper
 range for a computation.

 search order
 the sequence of default packages for a given
 domain to be searched during dynamic
 lookup. This sequence is computed first by ordering the category
 ancestors of the domain according to their
 <div class="gsyntax">level number</div>, an integer equal to to the
 minimum distance of the domain from the category. Parents have level
 1, parents of parents have level 2, and so on. Among categories with
 equal level numbers, ones which appear in the left-most branches of
 <div class="gsyntax">Join</div><div class="gspad">s</div> in the
 source code come first. See also dynamic lookup.

 search string
 a string entered into an input area on a screen

 selector
 an identifier used to address a component value of a
 Record datatype.

```

```

semantics
 the relationships between symbols and their meanings. The rules for
 obtaining the <div class="gsyntax">meaning</div> of any syntactically
 valid expression.

semigroup
 <div class="gsyntax">(algebra)</div> a monoid
 which need not have an identity; it is closed and associative.

side effect
 action which changes a component or structure of a value. See
 destructive operation for details.

signature
 <div class="gsyntax">(syntax)</div> an expression describing an
 operation. A signature has the form as
 <div class="gspad">name : source -> target</div>, where
 <div class="gspad">source</div> gives the type of the arguments of the
 operation, and <div class="gspad">target</div> gives the type of the
 result.

small float
 the domain for hardware floating point arithmetic as provided by the
 computer hardware.

small integer
 the domain for hardware integer arithmetic. as provided by the computer
 hardware.

source
 the type of the argument of a
 function; the type expression before the
 <div class="gspad">-></div> in a signature. For
 example, the source of
 <div class="gspad">f : (Integer, Integer) -> Integer</div>
 is <div class="gspad">(Integer, Integer)</div>.

sparse
 data structure whose elements are mostly identical (a sparse matrix
 is one filled with mostly zeroes).

static
 that computation done before run-time, such as compilation. Contrast
 dynamic.

```

```

step number
 the number which precedes user input lines in an interactive session;
 the output of user results is also labeled by this number.

stream
 an object of <div class="gtype">Stream(R)</div>, a generalization of
 a list to allow an infinite number of
 elements. Elements of a stream are computed "on demand". Strings are
 used to implement various forms of power series.

string
 an object of domain <div class="gtype">String</div>. Strings are
 literals consisting of an arbitrary sequence of
 characters surrounded by double-quotes
 (<div class="gfunction">"</div>), e.g.
 <div class="gspad">"Look here!"</div>.

subdomain
 <div class="gsyntax">(basic concept)</div> a
 domain together with a
 predicate characterizing which members of the
 domain belong to the subdomain. The exports of a subdomain are usually
 distinct from the domain itself. A fundamental assumption however is
 that values in the subdomain are automatically
 coerceable to values in the domain. For example, if
 <div class="gspad">n</div> and <div class="gspad">m</div> are declared
 to be members of a subdomain of the integers, then
 <div class="gsyntax">any</div> binary operation from
 <div class="gtype">Integer</div> is available on
 <div class="gspad">n</div> and <div class="gspad">m</div>. On the other
 hand, if the result of that operation is to be assigned to, say,
 <div class="gspad">k</div>, also declared to be of that subdomain, a
 run-time check is generally necessary to ensure
 that the result belongs to the subdomain.

substitution
 The right hand side of a rule is called the substitution.
 The left hand side of a rewrite rule is called a
 pattern. Rewrite rules
 can be used to perform pattern matching, usually for simplification.

such that clause
 the use of <div class="gfunction">|</div> followed by an expression
 to filter an iteration.

suffix

```

```

 <div class="gsyntax">(syntax)</div> an
 operator which placed after its operand. Suffix
 operators are not allowed in the Axiom language.

 symbol
 objects denoted by identifier
 literals; an element of domain
 <div class="gtype">Symbol</div>. The interpreter defaultly converts a
 symbol <div class="gspad">x</div> into
 <div class="gtype">Variable(x)</div>.

 syntax
 rules of grammar, punctuation etc. for forming correct expressions.

 system commands
 top-level Axiom statements that begin with
 <div class="gsyntax"></div>. System commands allow users to query the
 database, read files, trace functions, and so on.

 tag
 an identifier used to discriminate a branch of a
 Union type.

 target
 the type of the result of a
 function; the type expression following the
 <div class="gspad">-></div> in a signature.

 top-level
 refers to direct user interactions with the Axiom interpreter.

 totally ordered set
 <div class="gsyntax">(algebra)</div> a partially ordered set where
 any two elements are comparable.

 trace
 use of system function <div class="gcmd">)trace</div> to track the
 arguments passed to a function and the values returned.

 tuple
 an expression of two or more other expressions separated by commas,
 e.g. <div class="gspad">4, 7, 11</div>. Tuples are also used for
 multiple arguments both for applications
 (e.g. <div class="gspad">f(x, y)</div>) and in
 signatures (e.g.
 <div class="gspad">(Integer, Integer) -> Integer</div>).

```

A tuple is not a data structure, rather a syntax mechanism for grouping expressions.

**type**

The type of any [subdomain](#p48303) is the unique symbol [Category](#p17507). The type of a [domain](#p17507) is any [category](#p6628) that domain belongs to. The type of any other object is either the (unique) domain that object belongs to or any [subdomain](#p48303) of that domain. The type of objects is in general not unique.

**type checking**

a system function which determines whether the datatype of an object is appropriate for a given operation.

**type constructor**

a [domain constructor](#p16173) or [category constructor](#p8355).

**type inference**

when the interpreter chooses the type for an object based on context. For example, if the user interactively issues the definition  $f(x) == (x + i)^2$  then issues  $f(2)$ , the interpreter will infer the type of  $f$  to be `Integer -> Complex Integer`.

**unary**

operation or function with [arity](#p3173) 1

**underlying domain**

for a [domain](#p17507) that has a single domain-valued parameter, the [underlying domain](#) refers to that parameter. For example, the domain "matrices of integers" (`Matrix Integer`) has underlying domain `Integer`.

**Union**

[\(basic domain constructor\)](#) a domain constructor used to combine any set of domains into a single domain. A Union domain is written in the form  $\text{Union}(a_1:D_1, \dots, a_n:D_n)$  ( $n > 0$ ) where  $a_1, \dots, a_n$  are identifiers called the [tags](#) of the union, and  $D_1, \dots, D_n$  are

domains called the `<div class="gsyntax">branches</div>` of the union. The tags `<div class="gspad">ai</div>` are optional, but required when two of the `<div class="gspad">Di</div>` are equal, e.g. `<div class="gspad">Union(inches:Integer, centimeters:Integer)</div>`. In the interpreter, values of union domains are automatically coerced to values in the branches and vice-versa as appropriate. See also [case](#p6220).

`</li>`

`<li><a name="p52482" class="glabel"/><b>unit</b>`  
`<div class="gsyntax">(algebra)</div>` an invertible element.  
`</li>`

`<li><a name="p52526" class="glabel"/><b>user function</b>`  
 a function defined by a user during an interactive session. Contrast [built-in function](#p5399).  
`</li>`

`<li><a name="p52631" class="glabel"/><b>user variable</b>`  
 a variable created by the user at top-level during an interactive session  
`</li>`

`<li><a name="p52710" class="glabel"/><b>value</b>`  
`<ol>`  
`<li>`  
 the result of [evaluating](#p19167) an expression.  
`</li>`  
`<li>`  
 a property associated with a [variable](#p52894) in a [binding](#p4735) in an [environment](#p19131).  
`</li>`  
`</ol>`  
`</li>`

`<li><a name="p52894" class="glabel"/><b>variable</b>`  
 a means of referring to an object but itself is not an object. A variable has a name and an associated [binding](#p4735) created by [evaluation](#p19167) of Axiom expressions such as [declarations](#p12903), [assignments](#p3322), and [definitions](#p13754). In the top-level [environment](#p19131) of the interpreter, variables are [global variables](#p24833). Such variables can be freely referenced in user-defined functions although a [free](#p22113) declaration is needed to assign values to them. See [local variable](#p32278) for details.  
`</li>`

`<li><a name="p53484" class="glabel"/><b>Void</b>`  
 the type given when the [value](#p52710) and [type](#p50664) of an expression are not needed. Also used when there is no guarantee at run-time that a value and predictable

```

mode will result.

wild card
 a symbol which matches any substring including the empty string; for
 example, the search string <div class="gsyntax">*an*</div> matches an
 word containing the consecutive letters <div class="gsyntax">a</div>
 and <div class="gsyntax">n</div>

workspace
 an interactive record of the user input and output held in an
 interactive history file. Each user input and corresponding output
 expression in the workspace has a corresponding step
 number. The current output expression in the workspace is referred
 to as <div class="gspad">%</div>. The output expression associated
 with step number <div class="gspad">n</div> is referred to by <div
 class="gspad">%%(n)</div>. The <div class="gspad">k</div>-th previous
 output expression relative to the current step number <div
 class="gspad">n</div> is referred to by <div class="gspad">%%(-
 k)</div>. Each interactive frame has its own
 workspace.

 Here are some examples of Axiom graphics.

 Assorted Examples

 Examples of each type of Axiom Graphics

 Three Dimensional Graphics

 Plot parametrically defined surfaces of three functions.

 Functions of One Variable

 Plot curves defined by an equation $y=f(x)$

 Parametric Curves

 Plot curves defined by parametric equations $x=f(t)$, $y=f(t)$

 Polar Coordinates

 Plot curves given in polar form by an equation $r=f(\theta)$

 Implicit Curves

 Plot non-singular curves defined by a polynomial equation

 Lists of Points

 Plot lists of points in the (x,y) -plane

</graphicspage.xhtml>

```

## 1.9.350 graphviewports.xhtml

```

<graphviewports.xhtml>≡
 <standard head>
 <script type="text/javascript">
 <handlefreevars>
 <axiom talker>
 </script>
 </head>
 <body>
 <page head>
 <div align="center">Stand-alone Viewport</div>
 <hr/>

```

To get a viewport on a page, you first need to create one in Axiom and write it out to a file that can be called up. For example, we draw a saddle function and assign the result to the variable `v`.

```

 <input type="submit" id="p1" class="subbut"
 onclick="makeRequest('p1');"
 value="v:=draw(x*x-y*y,x=-1..1,y=-1..1)" />
 <div id="ansp1"><div></div></div>

```

Now that we've created the viewport, we want to write the data out to a file. To do this, we use the `<a href="dbopwrite.xhtml">write</a>` command which takes as arguments the viewport to write out, the title of the file to be written to, and an optional argument telling the write command what type (or types) of data you want to write (in addition to the ones that Axiom writes). The optional argument could be a string, like "pixmap", or a list of strings, like ["postscript", "pixmap"]. We need a "bitmap" data type to include a graph in a page so in this case, we write the viewport and tell it to also write a "pixmap" file:

```

 <input type="submit" id="p2" class="subbut"
 onclick="handleFree(['p1','p2']);"
 value='write(v,"saddle","bitmap")' />
 <div id="ansp2"><div></div></div>

```

Currently supported file formats are "pixmap", "bitmap", "postscript" and "image".

Axiom automatically adds ".view" at the end of the viewport data file to specify the file type. The ".view" is actually a directory and

contains a bitmap file, usually called image.bm.Z, which is a compressed bitmap. Firefox can display bitmap files, as shown here. Clicking on the image should start a "live graphics copy" so you can manipulate the image.

```

<handlefreevars>

```

## 1.9.352 graph2dimplicit.xhtml

```

<graph2dimplicit.xhtml>≡
 <standard head>
 <script type="text/javascript">
 <handlefreevars>
 <axiom talker>
 </script>
 </head>
 <body>
 <page head>
 <div align="center">Implicit Curves</div>
 <hr/>

```

Axiom has facilities for graphing a non-singular algebraic curve in a rectangular region of the plane. An algebraic curve is a curve defined by a polynomial equation  $p(x,y)=0$ . Non-singular means that the curve is "smooth" in that it does not cross itself or come to a point (cusp). Algebraically, this means that for any point  $(a,b)$  on the curve (i.e. a point such that  $p(a,b)=0$ ), the partial derivatives  $dp/dx(a,b)$  and  $dp/dy(a,b)$  are not both zero. We require that the polynomial have rational or integral coefficients. Here is a Cartesian ovals algebraic curve example:

```

 <input type="submit" id="p1" class="noresult"
 onclick="makeRequest('p1');"
 value="p:=((x^2+y^2+1)-8*x)^2-(8*(x^2+y^2+1)-4*x-1)" />
 <div id="ansp1"><div></div></div>

 <input type="submit" id="p2" class="subbut"
 onclick="handleFree(['p1','p2']);"
 value='draw(p=0,x,y,range==[-1..11,-7..7],title=="Cartesian Ovals")' />
 <div id="ansp2"><div></div></div>

```

A range must be declared for each variable specified in the algebraic curve equation.

```

<page foot>

```

$$\langle graph2dlistsofpoints.xhtml \rangle \equiv$$

Axiom has the ability to create lists of points in a two dimensional graphics viewport. This is done by utilizing the [GraphImage](db.xhtml?GraphImage) and [TwoDimensionalViewport](db.xhtml?TwoDimensionalViewport) domain facilities.

First we make a list of points

Then we select pairs of these points which represent the endpoints of lines.

Next we set the point color and size, and the line color for all components of the graph.

```

 <input type="submit" id="p3" class="noresult"
 onclick="makeRequest('p3');"
 value="lsize:=[6,6,6,6,8,8,8,8,10,10,10,10]" />
 <div id="ansp3"><div></div></div>

 <input type="submit" id="p4" class="noresult"
 onclick="makeRequest('p4');"
 value="pc1:=pastel red()" />
 <div id="ansp4"><div></div></div>

 <input type="submit" id="p5" class="noresult"
 onclick="makeRequest('p5');"
 value="pc2:=dim green()" />
 <div id="ansp5"><div></div></div>

 <input type="submit" id="p6" class="noresult"
 onclick="makeRequest('p6');"
 value="pc3:=pastel yellow()" />
 <div id="ansp6"><div></div></div>

 <input type="submit" id="p7" class="noresult"
 onclick="makeRequest('p7');"
 value="lpc:=[pc1,pc1,pc1,pc1,pc2,pc2,pc2,pc2,pc3,pc3,pc3,pc3]" />
 <div id="ansp7"><div></div></div>

 <input type="submit" id="p8" class="noresult"
 onclick="makeRequest('p8');"
 value="lc:=[pastel blue(), light yellow(), dim green(), bright red(), light green(), dim ye
 <div id="ansp8"><div></div></div>

```

Now the graph image is created and named according to the component specifications indicated above. The

[makeViewport2D](dbopmakeviewport2d.xhtml) command then creates a two dimensional viewport for this graph according to the list of options specified within the brackets.

```

 <input type="submit" id="p9" class="noresult"

```

```

 onclick="makeRequest('p9');"
 value="g:=makeGraphImage(llp,lpc,lc,lsize)$GRIMAGE" />
 <div id="ansp9"><div></div></div>

```

The `<a href="dbopmakeviewport2d.xhtml">makeViewport2D</a>` command takes a list of options as a parameter. In this example the string "Lines" is designated as the viewport's title.

```

 <input type="submit" id="p10" class="subbut"
 onclick="handleFree(['p1','p2','p3','p4','p5','p6','p7','p8','p9','p10']);"
 value='makeViewport2D(g,[title("Lines")])$VIEW2D' />
 <div id="ansp10"><div></div></div>

<page foot>

```

## 1.9.354 graph2donevariable.xhtml

`<graph2donevariable.xhtml>≡`

```

<standard head>
 <script type="text/javascript">
<handlefreevars>
<axiom talker>
 </script>
</head>
<body>
<page head>
 <div align="center">Functions of One Variable</div>
 <hr/>

```

Here we wish to plot a function  $y=f(x)$  on the interval  $[a,b]$ . As an example, let's take the function  $y=\sin(\tan(x))-\tan(\sin(x))$  on the interval  $[0,6]$ . Here is the simplest command that will do this:

```

 <input type="submit" id="p1" class="subbut"
 onclick="makeRequest('p1');"
 value="draw(sin(tan(x))-tan(sin(x)),x=0..6)" />
 <div id="ansp1"><div></div></div>

```

Notice that Axiom compiled a function before the graph was put on the screen. The expression  $\sin(\tan(x))-\tan(\sin(x))$  was converted to a compiled function so that its value for various values of  $x$  could be computed quickly and efficiently. Let's graph the same function on a different interval and this time we'll give the graph a title. The title is a string, which is an optional argument of the command 'draw'.

```

 <input type="submit" id="p2" class="subbut"
 onclick="makeRequest('p2');"
 value='draw(sin(tan(x))-tan(sin(x)),x=10..16,title=="y=sin tan x-tan sin x")'
 />
 <div id="ansp2"><div></div></div>

```

Once again the expression  $\sin(\tan(x))-\tan(\sin(x))$  was converted to a compiled function before any points were computed. If you want to graph the same function on a number of intervals, it's a good idea to write down a function definition so that the function only has to be compiled once.

Here's an example:

```

```

```

<input type="submit" id="p3" class="noresult"
 onclick="makeRequest('p3');"
 value="f(x)==(x-1)*(x-2)*(x-3)" />
<div id="ansp3"><div></div></div>

 <input type="submit" id="p4" class="subbut"
 onclick="handleFree(['p3','p4']);"
 value='draw(f,0..2,title=="y=f(x) on [0,2]")' />
 <div id="ansp4"><div></div></div>

 <input type="submit" id="p5" class="subbut"
 onclick="handleFree(['p3','p5']);"
 value='draw(f,0..4,title=="y=f(x) on [0,4]")' />
 <div id="ansp5"><div></div></div>

```

Notice that our titles can be whatever we want, as long as they are enclosed by double quotes. However, a title which is too long to fit within the viewport title window will be clipped.

*<page foot>*

## 1.9.355 graph2dparametric.xhtml

`<graph2dparametric.xhtml>≡`

```
<standard head>
 <script type="text/javascript">
<handlefreevars>
<axiom talker>
 </script>
</head>
<body>
<page head>
 <div align="center">Parametric Curves</div>
 <hr/>
```

One way of producing interesting curves is by using parametric equations. Let  $x=f(t)$  and  $y=g(t)$  for two functions  $f$  and  $g$  as the parameter  $t$  ranges over an interval  $[a,b]$ . Here's an example:

```

 <input type="submit" id="p1" class="subbut"
 onclick="makeRequest('p1');"
 value="draw(curve(sin(t)*sin(2*t)*sin(3*t),sin(4*t)*sin(5*t)*sin(6*t)),t=0..2*%pi)" />
 <div id="ansp1"><div></div></div>

```

Here  $0..2*\pi$  represents the interval over which the variable  $t$  ranges. In the case of parametric curves, Axiom will compile two functions, one for each of the functions  $f$  and  $g$ . You may also put a title on a graph. The title may be an arbitrary string and is an optional argument to the command 'draw'. For example:

```

 <input type="submit" id="p2" class="subbut"
 onclick="makeRequest('p2');"
 value='draw(curve(cos(t),sin(t)),t=0..2*%pi,title=="The Unit Circle")' />
 <div id="ansp2"><div></div></div>

```

If you plan on plotting  $x=f(t)$ ,  $y=g(t)$  as  $t$  ranges over several intervals, you may want to define functions  $f$  and  $g$ , so that they need not be recompiled every time you create a new graph. Here's an example:

```

 <input type="submit" id="p3" class="subbut"
 onclick="makeRequest('p3');"
 value="f(t:SF):SF == sin(3*t/4)" />
 <div id="ansp3"><div></div></div>
```

```

 <input type="submit" id="p4" class="subbut"
 onclick="makeRequest('p4');"
 value="g(t:SF):SF == sin(t)" />
 <div id="ansp4"><div></div></div>

 <input type="submit" id="p5" class="subbut"
 onclick="handleFree(['p3','p4','p5']);"
 value="draw(curve(f,g),0..%pi)" />
 <div id="ansp5"><div></div></div>

 <input type="submit" id="p6" class="subbut"
 onclick="handleFree(['p3','p4','p6']);"
 value="draw(curve(f,g),-%pi..2*%pi)" />
 <div id="ansp6"><div></div></div>

 <input type="submit" id="p7" class="subbut"
 onclick="handleFree(['p3','p4','p7']);"
 value="draw(curve(f,g),-4*%pi..4*%pi)" />
 <div id="ansp7"><div></div></div>

```

These examples show how the curve changes as the range of the parameter  $t$  varies.

*<page foot>*

## 1.9.356 graph2dpolar.xhtml

`<graph2dpolar.xhtml>≡`

`<standard head>`

`<script type="text/javascript">`

`<handlefreevars>`

`<axiom talker>`

`</script>`

`</head>`

`<body>`

`<page head>`

`<div align="center">Polar Coordinates</div>`

`<hr/>`

Graphs in polar coordinates are given by an equation  $r=f(\theta)$  as  $\theta$  ranges over an interval. This is equivalent to the parametric curve  $x=f(\theta)\cos(\theta)$ ,  $y=f(\theta)\sin(\theta)$  as  $\theta$  ranges over the same interval. You may create such curves using the command 'draw', with the optional argument 'coordinates==polar'.

Here are some examples:

`<ul>`

`<li>`

`<input type="submit" id="p1" class="subbut"`

`onclick="makeRequest('p1');"`

`value='draw(1,t=0..2*pi,coordinates==polar,title=="The Unit Circle")' />`

`<div id="ansp1"><div></div></div>`

`</li>`

`<li>`

`<input type="submit" id="p2" class="subbut"`

`onclick="makeRequest('p2');"`

`value='draw(sin(17*t),t=0..2*pi,coordinates==polar,title=="A Petal Curve")' />`

`<div id="ansp2"><div></div></div>`

`</li>`

`</ul>`

You may also define your own functions, when you plan on plotting the same curve as  $r=f(\theta)$ ; varies over several intervals.

`<ul>`

`<li>`

`<input type="submit" id="p3" class="noresult"`

`onclick="makeRequest('p3');"`

`value="f(t)==cos(4*t/7)" />`

`<div id="ansp3"><div></div></div>`

`</li>`

`<li>`

`<input type="submit" id="p4" class="subbut"`

`onclick="handleFree(['p3','p4']);"`

```

 value="draw(f,0..2*%pi,coordinates==polar)" />
 <div id="ansp4"><div></div></div>

 <input type="submit" id="p5" class="subbut"
 onclick="handleFree(['p3','p5']);"
 value="draw(f,0..14*%pi,coordinates==polar)" />
 <div id="ansp5"><div></div></div>

```

For information on plotting graphs in other coordinate systems see the pages for the [CoordinateSystems](db.xhtml?CoordinateSystems) domain.

*<page foot>*

### 1.9.357 graph3d.xhtml

```

<graph3d.xhtml>≡
 <standard head>
</head>
<body>
 <page head>
 <div align="center">Three Dimensional Graphing</div>
 <hr/>

 Functions of Two Variables

 Plot surfaces defined by an equation $z=f(x,y)$

 Parametric Curves

 Plot curves defined by equations $x=f(t)$, $y=g(t)$, $z=h(t)$

 Parametric Tube Plots

 Plot a tube around a parametric space curve

 Parametric Surfaces

 Plot surfaces defined by $x=f(u,v)$, $y=g(u,v)$, $z=h(u,v)$

 Building Objects

 Create objects constructed from geometric primitives

 <page foot>

```

## 1.9.358 graph3dobjects.xhtml

```

<graph3dobjects.xhtml>≡
 <standard head>
 <script type="text/javascript">
 <handlefreevars>
 <axiom talker>
 </script>
 </head>
 <body>
 <page head>
 <div align="center">Building Three Dimensional Objects from Primitives</div>
 <hr/>

```

Rather than using the `<a href="dbopdraw.xhtml">draw</a>` and `<a href="dbopmakeobject.xhtml">makeObject</a>` commands, you can create three-dimensional graphs from primitives. Operation `<a href="dbopcreate3space.xhtml">create3Space</a>` creates a three-space object to which points, curves, and polygons can be added using the operations from the `<a href="db.xhtml?ThreeSpace">ThreeSpace</a>` domain. The resulting object can then be displayed in a viewport using `<a href="dbopmakeviewport3d.xhtml">makeViewport3D</a>`.

Create the empty three-space object space.

```

 <input type="submit" id="p1" class="subbut"
 onclick="makeRequest('p1');"
 value="space:=create3Space()$(ThreeSpace DFLOAT)" />
 <div id="ansp1"><div></div></div>

```

Objects can be sent to this space using the operations exported by the `<a href="db.xhtml?ThreeSpace">ThreeSpace</a>` domain. The following examples place curves into space.

Add these three curves to the space.

```

 <input type="submit" id="p2" class="subbut"
 onclick="handleFree(['p1','p2']);"
 value="closedCurve(space,[[0,30,20],[0,30,30],[0,40,30],[0,40,100],[0,30,100],[0,30,110],[0,30,110],[0,30,20]])" />
 <div id="ansp2"><div></div></div>

 <input type="submit" id="p3" class="subbut"
 onclick="handleFree(['p1','p3']);"

```

```

 value="closedCurve(space,[[80,0,30],[80,0,100],[70,0,110],[40,0,110],[30,0,100]
<div id="ansp3"><div></div></div>

 <input type="submit" id="p4" class="subbut"
 onclick="handleFree(['p1','p4']);"
 value="closedCurve(space,[[70,0,35],[65,0,30],[45,0,30],[40,0,35],[40,0,60],[50
 <div id="ansp4"><div></div></div>

```

Create and display the viewport using

[makeViewport3D](dbopmakeviewport3d.xhtml)</a>. Options may also be given but here are displayed as a list with values enclosed in parentheses.

```

 <input type="submit" id="p5" class="subbut"
 onclick="handleFree(['p1','p2','p3','p4','p5']);"
 value='makeViewport3D(space,title=="Letters")' />
 <div id="ansp5"><div></div></div>

Cube Example

```

As a second example of the use of primitives, we generate a cube using a polygon mesh. It is important to use a consistent orientation of the polygons for correct generation of three-dimensional objects.

Again start with an empty three-space object.

```

 <input type="submit" id="p6" class="subbut"
 onclick="makeRequest('p6');"
 value="spaceC:=create3Space()$(ThreeSpace DFLOAT)" />
 <div id="ansp6"><div></div></div>

```

For convenience, give the [DoubleFloat](db.xhtml?DoubleFloat)</a> values +1 and -1 names.

```

 <input type="submit" id="p7" class="subbut"
 onclick="makeRequest('p7');"
 value="x:DFLOAT:=1" />
 <div id="ansp7"><div></div></div>

```

```

 <input type="submit" id="p8" class="subbut"
 onclick="makeRequest('p8');"
 value="y:DFLOAT:=-1" />
 <div id="ansp8"><div></div></div>

Define the vertices of the cube.

 <input type="submit" id="p9" class="subbut"
 onclick="handleFree(['p7','p8','p9']);"
 value="a:=point [x,x,y,1::DFLOAT]$(Point DFLOAT)" />
 <div id="ansp9"><div></div></div>

 <input type="submit" id="p10" class="subbut"
 onclick="handleFree(['p7','p8','p10']);"
 value="b:=point [y,x,y,4::DFLOAT]$(Point DFLOAT)" />
 <div id="ansp10"><div></div></div>

 <input type="submit" id="p11" class="subbut"
 onclick="handleFree(['p7','p8','p11']);"
 value="c:=point [y,x,x,8::DFLOAT]$(Point DFLOAT)" />
 <div id="ansp11"><div></div></div>

 <input type="submit" id="p12" class="subbut"
 onclick="handleFree(['p7','p8','p12']);"

### 1.9.359 graph3dparametric.xhtml

```

<graph3dparametric.xhtml>≡
 <standard head>
 <script type="text/javascript">
 <handlefreevars>
 <axiom talker>
 </script>
 </head>
 <body>
 <page head>
 <div align="center">Parametric Space Curves</div>
 <hr/>

```

This page describes the plotting in three dimensional space of a curve defined by the parametric equations  $x=f(t)$ ,  $y=g(t)$ ,  $z=h(t)$ , where  $f, g$ , and  $h$  are functions of the parameter  $t$  which ranges over a specified interval. The basic draw command for this function utilizes either the uncompiled functions or compiled functions format and uses the `<a href="dbopcurve.xhtml">curve</a>` command to specify the three functions for the  $x$ ,  $y$ , and  $z$  components of the curve. The general format for uncompiled functions is:

```

<pre>
 draw(curve(f(t),g(t),h(t)), t=a..b)
</pre>

```

where  $a..b$  is the segment defining the interval  $[a,b]$  over which the parameter  $t$  ranges. In this case the functions are not compiled until the draw command is executed. Here is an example:

```

 <input type="submit" id="p1" class="subbutt"
 onclick="makeRequest('p1');"
 value="draw(curve(cos(t),sin(t),t),t=-12..12)" />
 <div id="ansp1"><div></div></div>

```

In the case of compiled functions, the functions are named and compiled independently. This is useful if you intend to use the functions often, or if the functions are long and complex. The following lines show functions whose parameters are of the type `SmallFloat`. The functions are compiled and stored by Axiom when entered.

```

 <input type="submit" id="p2" class="noresult"
 onclick="makeRequest('p2');"
 value="i1(t:SF):SF==sin(t)*cos(3*t/5)" />
 <div id="ansp2"><div></div></div>

```

```

 <input type="submit" id="p3" class="noresult"
 onclick="makeRequest('p3');"
 value="i2(t:SF):SF==cos(t)*cos(3*t/5)" />
 <div id="ansp3"><div></div></div>

 <input type="submit" id="p4" class="noresult"
 onclick="makeRequest('p4');"
 value="i3(t:SF):SF==cos(t)*sin(3*t/5)" />
 <div id="ansp4"><div></div></div>

```

Once the functions are compiled the draw command only needs the names of the functions to execute. Here is a compiled functions example:

```

 <input type="submit" id="p5" class="subbut"
 onclick="handleFree(['p2','p3','p4','p5']);"
 value="draw(curve(i1,i2,i3),0..15*%pi)" />
 <div id="ansp5"><div></div></div>

```

Note that the parameter range does not take the variable name as in the case of uncompiled functions. It is understood that the indicated range applies to the parameter of the functions, which in this case is  $t$ .

*<page foot>*

## 1.9.360 graph3dsurfaces.xhtml

*(graph3dsurfaces.xhtml)*≡

```

<standard head>
 <script type="text/javascript">
 <handlefreevars>
 <axiom talker>
 </script>
</head>
<body>
 <page head>
 <div align="center">Parametric Surfaces</div>
 <hr/>

```

Graphing a surface defined by  $x=f(u,v)$ ,  $y=g(u,v)$ ,  $z=h(u,v)$ . This page describes plotting of surfaces defined by the parametric equations of two variables,  $x=f(u,v)$ ,  $y=g(u,v)$ , and  $z=h(u,v)$ , for which the ranges of  $u$  and  $v$  are explicitly defined. The basic draw command for this function utilizes either the uncompiled function or compiled function format and uses the `<a href="dbopsurface.xhtml">surface</a>` command to specify the three functions for the  $x$ ,  $y$ , and  $z$  components of the surface. The general format for uncompiled functions is:

```

<pre>
 draw(surface(f(u,v),g(u,v),h(u,v)), u=a..b, v=c..d)
</pre>

```

where  $a..b$  and  $c..d$  are segments defining the intervals  $[a,b]$  and  $[c,d]$  over which the parameters  $u$  and  $v$  span. In this case the functions are not compiled until the draw command is executed. Here is an example of a surface plotted using the parabolic cylindrical coordinate system option:

```

 <input type="submit" id="p1" class="subbutt"
 onclick="makeRequest('p1');"
 value="draw(surface(u*cos(v),u*sin(v),v*cos(u)),u=-4..4,v=0..2*pi,coordinates==parabolicCy
 <div id="ansp1"><div></div></div>

```

In the case of compiled functions, the functions are named and compiled independently. This is useful if you intend to use the functions often, or if the functions are long and complex. The following lines show functions whose parameters are of the type SmallFloat. The functions are compiled and stored by Axiom when entered.

```

 <input type="submit" id="p2" class="noresult"
 onclick="makeRequest('p2');"
 value="n1(u:SF,v:SF):SF == u*cos(v)" />

```

```

 <div id="ansp2"><div></div></div>

 <input type="submit" id="p3" class="noresult"
 onclick="makeRequest('p3');"
 value="n2(u:SF,v:SF):SF == u*sin(v)" />
 <div id="ansp3"><div></div></div>

 <input type="submit" id="p4" class="noresult"
 onclick="makeRequest('p4');"
 value="n3(u:SF,v:SF):SF == u" />
 <div id="ansp4"><div></div></div>

```

Once the function is compiled the draw command only needs the names of the functions to execute. Here is a compiled functions example plotted using the toroidal coordinate system option:

```

 <input type="submit" id="p5" class="subbut"
 onclick="handleFree(['p2','p3','p4','p5']);"
 value="draw(surface(n1,n2,n3),1.0..4.0,1.0..4*%pi,coordinates==toroidal(1$SF))" /
 <div id="ansp5"><div></div></div>

```

Note that the parameter ranges do not take the variable names as in the case of uncompiled functions. The variables are entered in the order in which they are defined in the function specification. In this case the first range specifies the u-variable and the second range specifies the v-variable.

*<page foot>*

### 1.9.361 graph3dtubeplots.xhtml

`<graph3dtubeplots.xhtml>≡`

```
<standard head>
 <script type="text/javascript">
<handlefreevars>
<axiom talker>
 </script>
</head>
<body>
<page head>
 <div align="center">Parametric Tube Plots</div>
 <hr/>
```

This page describes the plotting in three dimensional space of a tube around a parametric space curve defined by the parametric equations  $x=f(t)$ ,  $y=g(t)$ ,  $z=h(t)$ , where  $f$ ,  $g$ , and  $h$  are functions of the parameter  $t$  which ranges over a specified interval. The basic draw command for this function utilizes either the uncompiled functions or compiled functions format and uses the `<a href="dbopcurve.xhtml">curve</a>` command to specify the three functions for the  $x$ ,  $y$ , and  $z$  components of the curve. This uses the same format as that for space curves except that it requires a specification for the radius of the tube. If the radius of the tube is 0, then the result is the space curve itself. The general format for uncompiled functions is:

```
<pre>
 draw(curve(f(t),g(t),h(t)),t=a..b,tubeRadius==r)
</pre>
```

where  $a..b$  is the segment defining the interval  $[a,b]$  over which the parameter  $t$  ranges, and the `tubeRadius` is indicated by the variable  $r$ . In this case the functions are not compiled until the draw command is executed. Here is an example:

```

 <input type="submit" id="p1" class="subbut"
 onclick="makeRequest('p1');"
 value="draw(curve(sin(t)*cos(3*t/5),cos(t)*cos(3*t/5),cos(t)*sin(3*t/5)),t=0..15*%pi,tubeRa
 <div id="ansp1"><div></div></div>

```

In the case of compiled functions, the functions are named and compiled independently. This is useful if you intend to use the functions often, or if the functions are long and complex. The following lines show functions whose parameters are of the type `SmallFloat`. The functions are compiled and stored by Axiom when entered.

```

```

```

<div></div></div>

<div></div></div>

<div></div></div>

```

Once the function is compiled the draw command only needs the names of the functions to execute. Here is a compiled functions example of a trefoil knot:

```

<div></div></div>

```

Note that the parameter range does not take the variable name as in the case of uncompiled functions. It is understood that the indicated range applies to the parameter of the functions, which in this case is  $t$ . Typically, the radius of the tube should be set between 0 and 1. A radius of less than 0 results in it's positive counterpart and a radius of greater than one cause self-intersection.

*<page foot>*

## 1.9.362 graph3dtwovariables.xhtml

*(graph3dtwovariables.xhtml)*≡

```

<standard head>
 <script type="text/javascript">
 <handlefreevars>
 <axiom talker>
 </script>
</head>
<body>
 <page head>
 <div align="center">Functions of Two Variables</div>
 <hr/>

```

This page describes the plotting of surfaces defined by an equation of two variables,  $z=f(x,y)$ , for which the ranges of  $x$  and  $y$  are explicitly defined. The basic draw command for this function utilizes either the uncompiled function or compiled function format. The general format for an uncompiled function is:

```

<pre>
 draw(f(x,y), x=a..b, y=c..d)
</pre>

```

where  $a..b$  and  $c..d$  are segments defining the intervals  $[a,b]$  and  $[c,d]$  over which the variables  $x$  and  $y$  span. In this case, the function is not compiled until the draw command is executed. Here is an example:

```

 <input type="submit" id="p1" class="subbut"
 onclick="makeRequest('p1');"
 value="draw(cos(x*y),x=-3..3,y=-3..3)" />
 <div id="ansp1"><div></div></div>

```

In the case of a compiled function, the function is named and compiled independently. This is useful if you intend to use a function often, or if the function is long and complex. The following line shows a function whose parameters are of the type SmallFloat. The function is compiled and stored by Axiom when it is entered.

```

 <input type="submit" id="p2" class="noresult"
 onclick="makeRequest('p2');"
 value="f(x:SF,y:SF):SF==sin(x)*cos(y)" />
 <div id="ansp2"><div></div></div>

```

Once the function is compiled the draw command only needs the name of the

function to execute. Here is a compiled function example:

```

 <input type="submit" id="p3" class="subbut"
 onclick="handleFree(['p2','p3']);"
 value="draw(f,-%pi..%pi,-%pi..%pi)" />
 <div id="ansp3"><div></div></div>

```

Note that the parameter ranges do not take the variable names as in the case of uncompiled functions. The variables are entered in the order in which they are defined in the function specification. In this case the first range specifies the x-variable and the second range specifies the y-variable.

### 1.9.369 linconversion.xhtml

```

<linconversion.xhtml>≡
 <standard head>
 <script type="text/javascript">
 <handlefreevars>
 <axiom talker>
 </script>
 </head>
 <body>
 <page head>
 <div align="center">Conversion</div>
 <hr/>

```

Conversion is the process of changing an object of one type into an object of another type. The syntax for conversion is `object::newType`.  
 <hr/>

By default, 3 has the type

```

PositiveInteger

 <input type="submit" id="p1" class="subbut"
 onclick="makeRequest('p1');"
 value="3" />
 <div id="ansp1"><div></div></div>

```

We can change this into an object of type

```

Fraction Integer by using "::".

 <input type="submit" id="p2" class="subbut"
 onclick="makeRequest('p2');"
 value="3::Fraction Integer" />
 <div id="ansp2"><div></div></div>

```

A coercion is a special kind of conversion that Axiom is allowed to do automatically when you enter an expression. Coercions are usually somewhat safer than more general conversions. The Axiom library contains operations called

```

coerce and
convert. Only the
coerce operations can be used by the
interpreter to change an object into an object of another type unless
you explicitly use a "::".

```

By now you will be quite familiar with what types and modes look like. It is useful to think of a type or mode as a pattern for what you want the result to be. Let's start with a square matrix of polynomials with complex rational number coefficients.

```

 <input type="submit" id="p3" class="noresult"
 onclick="makeRequest('p3');"
 value="m:SquareMatrix(2,POLY COMPLEX FRAC INT)" />
 <div id="ansp3"><div></div></div>

 <input type="submit" id="p4" class="subbut"
 onclick="handleFree(['p3','p4']);"
 value="m:=matrix [[x-3/4*i,z*y^2+1/2],[3/7*i*y^4-x,12-%i*9/5]]" />
 <div id="ansp4"><div></div></div>

```

We first want to interchange the [Complex](db.xhtml?Complex) and [Fraction](db.xhtml?Fraction) layers. We do the conversion by doing the interchange in the type expression.

```

 <input type="submit" id="p5" class="subbut"
 onclick="handleFree(['p3','p4','p5']);"
 value="m1:=m::SquareMatrix(2,POLY FRAC COMPLEX INT)" />
 <div id="ansp5"><div></div></div>

```

Interchange the [Polynomial](db.xhtml?Polynomial) and the [Fraction](db.xhtml?Fraction) levels.

```

 <input type="submit" id="p6" class="subbut"
 onclick="handleFree(['p3','p4','p5','p6']);"
 value="m2:=m1::SquareMatrix(2,FRAC POLY COMPLEX INT)" />
 <div id="ansp6"><div></div></div>

```

Interchange the [Polynomial](db.xhtml?Polynomial) and the [Complex](db.xhtml?Complex) levels.

```

 <input type="submit" id="p7" class="subbut"
 onclick="handleFree(['p3','p4','p5','p6','p7']);"
 value="m3:=m2::SquareMatrix(2,FRAC COMPLEX POLY INT)" />
```

```

 <div id="ansp7"><div></div></div>

```

All the entries have changed types, although in comparing the last two results only the entry in the lower left corner looks different. We did all the intermediate steps to show you what Axiom can do.

In fact, we could have combined all these into one conversion.

```

 <input type="submit" id="p8" class="subbut"
 onclick="handleFree(['p3','p4','p8']);"
 value="m::SquareMatrix(2,FRAC COMPLEX POLY INT)" />
 <div id="ansp8"><div></div></div>

```

There are times when Axiom is not able to do the conversion in one step. You may need to break up the transformation into several conversions in order to get an object of the desired type.

We cannot move either the [Fraction](db.xhtml?Fraction) or [Complex](db.xhtml?Complex) above (or to the left of, depending on how you look at it) [SquareMatrix](db.xhtml?SquareMatrix) because each of these levels requires that its argument type have commutative multiplication, whereas [SquareMatrix](db.xhtml?SquareMatrix) does not. ([Fraction](db.xhtml?Fraction) requires that its argument belong to the category [IntegralDomain](db.xhtml?IntegralDomain) and [Complex](db.xhtml?Complex) requires that its argument belongs to [CommutativeRing](db.xhtml?CommutativeRing). See the [Jenks section 2.1](axbook/section-2.1.xhtml) for a brief discussion of categories. The [Integer](db.xhtml?Integer) level did not move anywhere because it does not allow any arguments. We also did not move the [SquareMatrix](db.xhtml?SquareMatrix) part anywhere, but we could have. Recall that `m` looks like this:

```

 <input type="submit" id="p9" class="subbut"
 onclick="handleFree(['p3','p4','p9']);"
 value="m" />
 <div id="ansp9"><div></div></div>

```

If we want a polynomial with matrix coefficients rather than a matrix with

polynomial entries, we can just do the conversion.

```

 <input type="submit" id="p10" class="subbut"
 onclick="handleFree(['p3','p4','p10']);"
 value="m::POLY SquareMatrix(2,COMPLEX FRAC INT)" />
 <div id="ansp10"><div></div></div>

```

We have not yet used modes for any conversions. Modes are a great shorthand for indicating the type of the object you want. Instead of using the long type expression in the last example we could have simply said this:

```

 <input type="submit" id="p11" class="subbut"
 onclick="handleFree(['p3','p4','p11']);"
 value="m::POLY ?" />
 <div id="ansp11"><div></div></div>

```

We can also indicate more structure if we want the entries of the matrices to be fractions.

```

 <input type="submit" id="p12" class="subbut"
 onclick="handleFree(['p3','p4','p12']);"
 value="m::POLY SquareMatrix(2,FRAC ?)" />
 <div id="ansp12"><div></div></div>

```

*<page foot>*

### 1.9.370 lincreate.xhtml

```

<lincreate.xhtml>≡
 <standard head>
 <script type="text/javascript">
 <handlefreevars>
 <axiom talker>
 </script>
 </head>
 <body onload="resetvars();">
 <page head>
 <div align="center">Creating Matrices</div>
 <hr/>

```

There are many ways to create a matrix from a collection of values or from existing matrices.

If the matrix has almost all items equal to the same value, use  
[new](dbopnew.xhtml) to create a matrix filled with that value  
 and then reset the entries that are different.

```

 <input type="submit" id="p1" class="subbut"
 onclick="makeRequest('p1');"
 value="m:Matrix(Integer):=new(3,3,0)" />
 <div id="ansp1"><div></div></div>

```

To change the entry in the second row, third column to 5, use  
[setelt](dbopsetelt.xhtml).

```

 <input type="submit" id="p2" class="subbut"
 onclick="handleFree(['p1','p2']);"
 value="setelt(m,2,3,5)" />
 <div id="ansp2"><div></div></div>

```

An alternative syntax is to use assignment.

```

 <input type="submit" id="p3" class="subbut"
 onclick="handleFree(['p1','p3']);"
 value="m(1,2):=10" />
 <div id="ansp3"><div></div></div>

```

The matrix was destructively modified.

```

 <input type="submit" id="p4" class="subbut"
 onclick="handleFree(['p1','p4']);"
 value="m" />
 <div id="ansp4"><div></div></div>

```

If you already have the matrix entries as a list of lists, use  
[matrix](dbopmatrix.xhtml).

```

 <input type="submit" id="p5" class="subbut"
 onclick="makeRequest('p5');"
 value="matrix [[1,2,3,4],[0,9,8,7]]" />
 <div id="ansp5"><div></div></div>

```

If the matrix is diagonal, use

[diagonalMatrix](dbopdiagonalmatrix.xhtml)

```

 <input type="submit" id="p6" class="subbut"
 onclick="makeRequest('p6');"
 value="dm:=diagonalMatrix [1,x^2,x^3,x^4,x^5]" />
 <div id="ansp6"><div></div></div>

```

Use [setRow!](dbopsetrowbang.xhtml) and

[setColumn!](dbopsetcolumnbang.xhtml)

to change a row or column of a matrix.

```

 <input type="submit" id="p7" class="subbut"
 onclick="handleFree(['p6','p7']);"
 value="setRow!(dm,5,vector [1,1,1,1,1])" />
 <div id="ansp7"><div></div></div>

 <input type="submit" id="p8" class="subbut"
 onclick="handleFree(['p6','p7','p8']);"
 value="setColumn!(dm,2,vector [y,y,y,y,y])" />
 <div id="ansp8"><div></div></div>

```

Use `<a href="dbopcopy.xhtml">copy</a>` to make a copy of a matrix.

```

 <input type="submit" id="p9" class="subbut"
 onclick="handleFree(['p6','p7','p8','p9']);"
 value="cdm:=copy(dm)" />
 <div id="ansp9"><div></div></div>

```

This is useful if you intend to modify a matrix destructively but want a copy of the original.

```

 <input type="submit" id="p10" class="subbut"
 onclick="handleFree(['p6','p7','p8','p9','p10']);"
 value="setelt(dm,4,1,1-x^7)" />
 <div id="ansp10"><div></div></div>

 <input type="submit" id="p11" class="subbut"
 onclick="handleFree(['p6','p7','p8','p9','p10','p11']);"
 value="[dm,cdm]" />
 <div id="ansp11"><div></div></div>

```

Use `<a href="dbopsubmatrix.xhtml">subMatrix</a>(dm,2,3,2,4)` to extract part of an existing matrix. The syntax is

```
<pre>
 subMatrix(m,firstrow,lastrow,firstcol,lastcol)
</pre>

 <input type="submit" id="p12" class="subbut"
 onclick="handleFree(['p6','p7','p8','p9','p10','p11','p12']);"
 value="subMatrix(dm,2,3,2,4)" />
 <div id="ansp12"><div></div></div>

```

To change a submatrix, use

`<a href="dbopsetsubmatrixbang.xhtml">setsubMatrix!</a>`.

```

 <input type="submit" id="p13" class="subbut"
 onclick="makeRequest('p13');"
 value="d:=diagonalMatrix [1.2,-1.3,1.4,-1.5]" />
 <div id="ansp13"><div></div></div>
```

```

If e is too big to fit where you specify, an error message is displayed. Use
subMatrix.

 <input type="submit" id="p14" class="subbut"
 onclick="makeRequest('p14');"
 value="e:=matrix [[6.7,9.11],[-31.33,67.19]]" />
 <div id="ansp14"><div></div></div>

This changes the submatrix of d whose upper left corner is at the first row
and second column and whose size is that of e.

 <input type="submit" id="p15" class="subbut"
 onclick="handleFree(['p13','p14','p15']);"
 value="setsubMatrix!(d,1,2,e)" />
 <div id="ansp15"><div></div></div>

 <input type="submit" id="p16" class="subbut"
 onclick="handleFree(['p13','p14','p15','p16']);"
 value="d" />
 <div id="ansp16"><div></div></div>

Matrices can be joined either horizontally or vertically to make new
matrices.

 <input type="submit" id="p17" class="subbut"
 onclick="makeRequest('p17');"
 value="a:=matrix [[1/2,1/3,1/4],[1/5,1/6,1/7]]" />
 <div id="ansp17"><div></div></div>

 <input type="submit" id="p18" class="subbut"
 onclick="makeRequest('p18');"
 value="b:=matrix [[3/5,3/7,3/11],[3/13,3/17,3/19]]" />
 <div id="ansp18"><div></div></div>

```

Use `<a href="dbophorizconcat.xhtml">horizConcat</a>` to append them side to side. The two matrices must have the same number of rows.

```

 <input type="submit" id="p19" class="subbut"
 onclick="handleFree(['p17','p18','p19']);"
 value="horizConcat(a,b)" />
 <div id="ansp19"><div></div></div>

```

Use `<a href="dbopvertconcat.xhtml">vertConcat</a>` to stack one upon the other. The two matrices must have the same number of columns.

```

 <input type="submit" id="p20" class="subbut"
 onclick="handleFree(['p17','p18','p20']);"
 value="vab:=vertConcat(a,b)" />
 <div id="ansp20"><div></div></div>

```

The operation `<a href="dboptranspose.xhtml">transpose</a>` is used to create a new matrix by reflection across the main diagonal.

```

 <input type="submit" id="p21" class="subbut"
 onclick="handleFree(['p17','p18','p20','p21']);"
 value="transpose vab" />
 <div id="ansp21"><div></div></div>

```

*<page foot>*

## 1.9.371 lineigen.xhtml

```

<lineigen.xhtml>≡
 <standard head>
 <script type="text/javascript">
 <handlefreevars>
 <axiom talker>
 </script>
 </head>
 <body onload="resetvars();">
 <page head>
 <div align="center">Computation of Eigenvalues and Eigenvectors</div>
 <hr/>

```

In this section we show you some of Axiom's facilities for computing and manipulating eigenvalues and eigenvectors, also called characteristic values and characteristic vectors, respectively.

Let's first create a matrix with integer entries.

```

 <input type="submit" id="p1" class="subbut"
 onclick="makeRequest('p1');"
 value="m1:=matrix [[1,2,1],[2,1,-2],[1,-2,4]]" />
 <div id="ansp1"><div></div></div>

```

To get a list of the rational eigenvalues, use the operation

[eigenvalues](dbopeigenvalues.xhtml).

```

 <input type="submit" id="p2" class="subbut"
 onclick="handleFree(['p1','p2']);"
 value="leig:=eigenvalues(m1)" />
 <div id="ansp2"><div></div></div>

```

Given an explicit eigenvalue,

[eigenvector](dbopeigenvector.xhtml) computes the eigenvectors corresponding to it.

```

 <input type="submit" id="p3" class="subbut"
 onclick="handleFree(['p1','p2','p3']);"
 value="eigenvector(first(leig),m1)" />
 <div id="ansp3"><div></div></div>

```

</ul>

The operation [eigenvectors](dbopeigenvectors.xhtml) returns a list of pairs of values and vectors. When an eigenvalue is rational, Axiom gives you the value explicitly; otherwise, its minimal polynomial is given, (the polynomial of lowest degree with the eigenvalues as roots), together with a parametric representation of the eigenvector using the eigenvalue. This means that if you ask Axiom to [solve](dbopsolve.xhtml) the minimal polynomial, then you can substitute these roots into the parametric form of the corresponding eigenvectors.

You must be aware that unless an exact eigenvalue has been computed, the eigenvector may be badly in error.

<ul>

<li>

```

```

```

<div></div></div>

```

</li>

</ul>

Another possibility is to use the operation

[radicalEigenvectors](dbopradicaleigenvectors.xhtml) tries to compute explicitly the eigenvectors in terms of radicals.

<ul>

<li>

```

```

```

<div></div></div>

```

</li>

</ul>

Alternatively, Axiom can compute real or complex approximations to the eigenvectors and eigenvalues using the operations

[realEigenvectors](dboprealeigenvectors.xhtml) or

[complexEigenvectors](dbopcomplexeigenvectors.xhtml). They

each take an additional argument epsilon to specify the "precision"

required. In the real case, this means that each approximation will be

within plus or minus epsilon of the actual result. In the complex case, this

means that each approximation will be within plus or minus epsilon of the

actual result in each of the real and imaginary parts.

The precision can be specified as a [Float](db.xhtml?Float) if the results are desired in floating-point notation, or as

[Fraction Integer](dbfractioninteger.xhtml) if the results are to be expressed using rational (or complex rational) numbers.

<ul>

```

 <input type="submit" id="p6" class="subbut"
 onclick="handleFree(['p1','p6']);"
 value="realEigenvectors(m1,1/1000)" />
 <div id="ansp6"><div></div></div>

```

```

```

If an  $n$  by  $n$  matrix has  $n$  distinct eigenvalues (and therefore  $n$  eigenvectors) the operation [eigenMatrix](dbopeigenmatrix.xhtml) gives you a matrix of the eigenvectors.

```

 <input type="submit" id="p7" class="subbut"
 onclick="handleFree(['p1','p7']);"
 value="eigenMatrix(m1)" />
 <div id="ansp7"><div></div></div>

```

```

 <input type="submit" id="p8" class="subbut"
 onclick="makeRequest('p8');"
 value="m2:=matrix [[-5,-2],[18,7]]" />
 <div id="ansp8"><div></div></div>

```

```

 <input type="submit" id="p9" class="subbut"
 onclick="handleFree(['p8','p9']);"
 value="eigenMatrix(m2)" />
 <div id="ansp9"><div></div></div>

```

```

```

If a symmetric matrix has a basis of orthonormal eigenvectors, then [orthonormalBasis](dboporthonormalbasis.xhtml) computes a list of these vectors.

```

 <input type="submit" id="p10" class="subbut"
 onclick="makeRequest('p10');"
 value="m3:=matrix [[1,2],[2,1]]" />
 <div id="ansp10"><div></div></div>

```

```

 <input type="submit" id="p11" class="subbut"
 onclick="handleFree(['p10','p11']);"
 value="orthonormalBasis(m3)" />
 <div id="ansp11"><div></div></div>

```

</ul>

⟨*page foot*⟩

## 1.9.372 linhilbert.xhtml

```

<linhilbert.xhtml>≡
 <standard head>
 <script type="text/javascript">
 <handlefreevars>
 <axiom talker>
 </script>
 </head>
 <body onload="resetvars();">
 <page head>
 <div align="center">An Example: Determinant of a Hilbert Matrix</div>
 <hr/>
 Consider the problem of computing the determinant of a 10 by 10 Hilbert
 matrix. The (i,j)-th entry of a Hilbert matrix is given by $1/(i+j+1)$.

 First do the computation using rational numbers to obtain the exact result.

 <input type="submit" id="p1" class="subbut"
 onclick="makeRequest('p1');"
 value="a:MATRIX FRAC INT:=matrix [[1/(i+j+1) for j in 0..9] for i in 0..9]" />
 <div id="ansp1"><div></div></div>

 <input type="submit" id="p2" class="subbut"
 onclick="handleFree(['p1','p2']);"
 value="d:=determinant a" />
 <div id="ansp2"><div></div></div>

 <input type="submit" id="p3" class="subbut"
 onclick="handleFree(['p1','p2','p3']);"
 value="d::Float" />
 <div id="ansp3"><div></div></div>

 <input type="submit" id="p4" class="subbut"
 onclick="makeRequest('p4');"
 value=
 "b:Matrix DFLOAT:=matrix [[1/(i+j+1$DFLOAT) for j in 0..9] for i in 0..9]"/>
 <div id="ansp4"><div></div></div>

```

The result given by hardware floats is correct only to four significant digits of precision. In the jargon of numerical analysis, the Hilbert matrix is said

to be "ill-conditioned".

```

 <input type="submit" id="p5" class="subbut"
 onclick="handleFree(['p4','p5']);"
 value="determinant b" />
 <div id="ansp5"><div></div></div>

```

Now repeat the computation at a higher precision using Float.

```

 <input type="submit" id="p6" class="subbut"
 onclick="makeRequest('p6');"
 value="digits 40" />
 <div id="ansp6"><div></div></div>

 <input type="submit" id="p7" class="subbut"
 onclick="handleFree(['p6','p7']);"
 value=
 "c:Matrix Float:=matrix [[1/(i+j+1$Float) for j in 0..9] for i in 0..9]" />
 <div id="ansp7"><div></div></div>

 <input type="submit" id="p8" class="subbut"
 onclick="handleFree(['p6','p7','p8']);"
 value="determinant c" />
 <div id="ansp8"><div></div></div>

```

Reset [digits](dbopdigits.xhtml) to its default value.

```

 <input type="submit" id="p9" class="subbut"
 onclick="makeRequest('p9');"
 value="digits 20" />
 <div id="ansp9"><div></div></div>

```

*<page foot>*

## 1.9.373 linintro.xhtml

```

<linintro.xhtml>≡
 <standard head>
 <script type="text/javascript">
 <handlefreevars>
 <axiom talker>
 </script>
 </head>
 <body onload="resetvars();">
 <page head>
 <div align="center">Expanding to Higher Dimensions</div>
 <hr/>

```

To get higher dimensional aggregates, you can create one-dimensional aggregates with elements that are themselves aggregates, for example, lists of list, one-dimensional arrays of list of multisets, and so on. For applications requiring two-dimensional homogeneous aggregates, you will likely find two-dimensional arrays and matrices useful.

The entries in [TwoDimensionalArray](db.xhtml?TwoDimensionalArray) and [Matrix](?Matrix) objects are all the same type, except that those for [Matrix](db.xhtml?Matrix) must belong to a [Ring](db.xhtml?Ring). You create and access elements in roughly the same way. Since matrices have an understood algebraic structure, certain algebraic operations are available for matrices but not for arrays. Because of this, we limit our discussion here to [Matrix](db.xhtml?Matrix), that can be regarded as an extension of

[TwoDimensionalArray](db.xhtml?TwoDimensionalArray). See [TwoDimensionalArray](pagetwodimensionalarray.xhtml)

For more

information about Axiom's linear algebra facilities see

[Matrix](pagematrix.xhtml),  
[Permanent](pagepermanent.xhtml),  
[SquareMatrix](pagesquarematrix.xhtml),  
[Vector](pagevector.xhtml),

Computation of Eigenvalues and Eigenvectors

Solution of Linear and Polynomial Equations.

You can create a matrix from a list of lists, where each of the inner lists represents a row of the matrix.

```

 <input type="submit" id="p1" class="subbut"
 onclick="makeRequest('p1');">

```

```

 value="m:=matrix([[1,2],[3,4]])" />
 <div id="ansp1"><div></div></div>

 The "collections" construct (see

 Creating Lists and Streams with Iterators)
 is useful for creating matrices whose entries are given by formulas.

 <input type="submit" id="p2" class="subbut"
 onclick="makeRequest('p2');"
 value="matrix([[1/(i+j-x) for i in 1..4] for j in 1..4]])" />
 <div id="ansp2"><div></div></div>

 Let vm denote the three by three Vandermonde matrix.

 <input type="submit" id="p3" class="subbut"
 onclick="makeRequest('p3');"
 value="vm:=matrix [[1,1,1],[x,y,z],[x*x,y*y,z*z]]" />
 <div id="ansp3"><div></div></div>

 Use this syntax to extract an entry in the matrix.

 <input type="submit" id="p4" class="subbut"
 onclick="handleFree(['p3','p4']);"
 value="vm(3,3)" />
 <div id="ansp4"><div></div></div>

 You can also pull out a row or a column.

 <input type="submit" id="p5" class="subbut"
 onclick="handleFree(['p3','p5']);"
 value="column(vm,2)" />
 <div id="ansp5"><div></div></div>

 You can do arithmetic.

```

```

 <input type="submit" id="p6" class="subbut"
 onclick="handleFree(['p3','p6']);"
 value="vm*vm" />
 <div id="ansp6"><div></div></div>

You can perform operations such as
transpose,
trace, and
determinant

 <input type="submit" id="p7" class="subbut"
 onclick="handleFree(['p3','p7']);"
 value="factor determinant vm" />
 <div id="ansp7"><div></div></div>

<page foot>

```

### 1.9.374 linoperations.xhtml

```

<linoperations.xhtml>≡
 <standard head>
 <script type="text/javascript">
 <handlefreevars>
 <axiom talker>
 </script>
 </head>
 <body onload="resetvars();">
 <page head>
 <div align="center">Operations on Matrices</div>
 <hr/>
 Axiom provides both left and right scalar multiplication.

 <input type="submit" id="p1" class="subbut"
 onclick="makeRequest('p1');"
 value="m:=matrix [[1,2],[3,4]]" />
 <div id="ansp1"><div></div></div>

 <input type="submit" id="p2" class="subbut"
 onclick="handleFree(['p1','p2']);"
 value="4*m*(-5)" />
 <div id="ansp2"><div></div></div>

 You can add, subtract, and multiply matrices provided, of course, that the
 matrices have compatible dimensions. If not, an error message is displayed.

 <input type="submit" id="p3" class="subbut"
 onclick="makeRequest('p3');"
 value="n:=matrix([[1,0,-2],[-3,5,1]])" />
 <div id="ansp3"><div></div></div>

 This following product is defined but n*m is not.

 <input type="submit" id="p4" class="subbut"
 onclick="handleFree(['p1','p3','p4']);"
 value="m*n" />
 <div id="ansp4"><div></div></div>

```

</ul>

The operations [nrows](dbopnrows.xhtml) and [ncols](dbopncols.xhtml) return the number of rows and columns of a matrix. You can extract a row or a column of a matrix using the operations [row](dboprow.xhtml) and [column](dbopcolumn.xhtml). The object returned is a [Vector](db.xhtml?Vector). Here is the third column of the matrix n.

<ul>

<li>

```

<div></div></div>

```

</li>

</ul>

You can multiply a matrix on the left by a "row vector" and on the right by a "column vector".

<ul>

<li>

```

<div></div></div>

```

</li>

</ul>

The operation [inverse](dbopinverse.xhtml) computes the inverse of a matrix if the matrix is invertible, and returns "failed" if not. This Hilbert matrix is invertible.

<ul>

<li>

```

<div></div></div>

```

</li>

<li>

```

<div></div></div>

```

</li>

</ul>

This matrix is not invertible.

<ul>

<li>

```

```

```

 onclick="makeRequest('p9');"
 value="mm:=matrix([[1,2,3,4],[5,6,7,8],[9,10,11,12],[13,14,15,16]])" />
<div id="ansp9"><div></div></div>

 <input type="submit" id="p10" class="subbut"
 onclick="handleFree(['p9','p10']);"
 value="inverse(mm)" />
 <div id="ansp10"><div></div></div>

```

The operation [determinant](dbopdeterminant.xhtml) computes the determinant of a matrix provided that the entries of the matrix belong to a [CommutativeRing](db.xhtml?CommutativeRing). The above matrix `mm` is not invertible and, hence, must have determinant 0.

```

 <input type="submit" id="p11" class="subbut"
 onclick="handleFree(['p9','p11']);"
 value="determinant(mm)" />
 <div id="ansp11"><div></div></div>

```

The operation [trace](dboptrace.xhtml) computes the trace of a square matrix.

```

 <input type="submit" id="p12" class="subbut"
 onclick="handleFree(['p9','p12']);"
 value="trace(mm)" />
 <div id="ansp12"><div></div></div>

```

The operation [rank](dbopranks.xhtml) computes the rank of a matrix: the maximal number of linearly independent rows or columns.

```

 <input type="submit" id="p13" class="subbut"
 onclick="handleFree(['p9','p13']);"
 value="rank(mm)" />
 <div id="ansp13"><div></div></div>

```

The operation [nullity](dbopnullity.xhtml) computes the nullity of a matrix: the dimension of its null space.

```

```

```

 <input type="submit" id="p14" class="subbut"
 onclick="handleFree(['p9','p14']);"
 value="nullity(mm)" />
 <div id="ansp14"><div></div></div>

```

The operation [nullSpace](dbopnullspace.xhtml) returns a list containing a basis for the null space of a matrix. Note that the nullity is the number of elements in a basis for the null space.

```

 <input type="submit" id="p15" class="subbut"
 onclick="handleFree(['p9','p15']);"
 value="nullSpace(mm)" />
 <div id="ansp15"><div></div></div>

```

The operation [rowEchelon](dboprowechelon.xhtml) returns the row echelon form of a matrix. It is easy to see that the rank of this matrix is two and that its nullity is also two.

```

 <input type="submit" id="p16" class="subbut"
 onclick="handleFree(['p9','p16']);"
 value="rowEchelon(mm)" />
 <div id="ansp16"><div></div></div>

```

```

## 1.9.375 linpermaent.xhtml

*(linpermaent.xhtml)*≡

```

<standard head>
 <script type="text/javascript">
 <handlefreevars>
 <axiom talker>
 </script>
</head>
<body onload="resetvars();">
 <page head>
 <div align="center">Permanent</div>
 <hr/>

```

The package [Permanent](db.xhtml?Permanent) provides the function [permanent](dboppermanent.xhtml) for square matrices. The [permanent](dboppermanent.xhtml) of a square matrix can be computed in the same way as the determinant by expansion of minors except that for the permanent the sign for each element is 1, rather than being 1 if the row plus column indices is positive and -1 otherwise. This function is much more difficult to compute efficiently than the [determinant](dbopddeterminant.xhtml). An example of the use of [permanent](dboppermanent.xhtml) is the calculation of the *n*th derangement number, defined to be the number of different possibilities for *n* couples to dance but never with their own spouse. Consider an *n* by *x* matrix with entries 0 on the diagonal and 1 elsewhere. Think of the rows as one-half of each couple (for example, the males) and the columns the other half. The permanent of such a matrix gives the desired derangement number.

```

 <input type="submit" id="p1" class="noresult"
 onclick="makeRequest('p1');"
 value=
 "kn n == (r:MATRIX INT:=new(n,n,1); for i in 1..n repeat r.i.i:=0; r)" />
 <div id="ansp1"><div></div></div>

```

Here are some derangement numbers, which you see grow quite fast.

```

 <input type="submit" id="p2" class="subbut"
 onclick="handleFree(['p1','p2']);"
 value="permanent(kn(5)::SQMATRIX(5,INT))" />
 <div id="ansp2"><div></div></div>

 <input type="submit" id="p3" class="subbut"

```

```

 onclick="handleFree(['p1','p3']);"
 value="[permanent(kn(n)::SQMATRIX(n,INT)) for n in 1..13]" />
 <div id="ansp3"><div></div></div>

<page foot>

```

## 1.9.376 linsquarematrices.xhtml

*(linsquarematrices.xhtml)*≡

```

<standard head>
 <script type="text/javascript">
<handlefreevars>
<axiom talker>
 </script>
</head>
<body onload="resetvars();">
<page head>
 <div align="center">SquareMatrix</div>
 <hr/>

```

The top level matrix type in Axiom is

[Matrix](db.xhtml?Matrix), see  
 ([Matrix](db.xhtml?Matrix)), which provides basic arithmetic  
 and linear algebra functions. However, since the matrices can be of any  
 size it is not true that any pair can be added or multiplied. Thus  
[Matrix](db.xhtml?Matrix) has little algebraic structure.

Sometimes you want to use matrices as coefficients for polynomials or in  
 other algebraic contexts. In this case,

[SquareMatrix](db.xhtml?SquareMatrix) should be used. The  
 domain [SquareMatrix\(n,R\)](db.xhtml?SquareMatrix) gives the  
 ring of n by n square matrices over R.

```

 <input type="submit" id="p1" class="subbut"
 onclick="makeRequest('p1');"
 value="m:=squareMatrix [[1,-%i],[%i,4]]" />
 <div id="ansp1"><div></div></div>

```

The usual arithmetic operations are available.

```

 <input type="submit" id="p2" class="subbut"
 onclick="handleFree(['p1','p2']);"
 value="m*m-m" />
 <div id="ansp2"><div></div></div>

```

Square matrices can be used where ring elements are required. For example,  
 here is a matrix with matrix entries.

```

```

```

<input type="submit" id="p3" class="subbut"
 onclick="handleFree(['p1','p3']);"
 value="mm:=squareMatrix [[m,1],[1-m,m^2]]" />
<div id="ansp3"><div></div></div>

```

Or you can construct a polynomial with square matrix coefficients.

```

 <input type="submit" id="p4" class="subbut"
 onclick="handleFree(['p1','p4']);"
 value="p:=(x+m)^2" />
 <div id="ansp4"><div></div></div>

```

This value can be converted to a square matrix with polynomial coefficients.

```

 <input type="submit" id="p5" class="subbut"
 onclick="handleFree(['p1','p4','p5']);"
 value="p:=SquareMatrix(2,?)" />
 <div id="ansp5"><div></div></div>

```

For more information on related topics see

```

Modes and
Matrix. Issue the system command

```

```

 <input type="submit" id="p6" class="subbut"
 onclick="showcall('p6');"
 value=")show SquareMatrix"/>
 <div id="ansp6"><div></div></div>

```

to display the full list of operations defined by

```

SquareMatrix.

```

*<page foot>*

## 1.9.377 linvectors.xhtml

```

<linvectors.xhtml>≡
 <standard head>
 <script type="text/javascript">
 <handlefreevars>
 <axiom talker>
 </script>
 </head>
 <body onload="resetvars();">
 <page head>
 <div align="center">Vector</div>
 <hr/>

```

The [Vector](db.xhtml?Vector) domain is used for storing data in a one-dimensional indexed data structure. A vector is a homogeneous data structure in that all the components of the vector must belong to the same Axiom domain. Each vector has a fixed length specified by the user; vectors are not extensible. This domain is similar to the

[OneDimensionalArray](db.xhtml?OneDimensionalArray) domain, except that when the components of a [Vector](db.xhtml?Vector) belong to a [Ring](db.xhtml?Ring), arithmetic operations are provided. For more examples of operations that are defined for both [Vector](db.xhtml?Vector) and [OneDimensionalArray](db.xhtml?OneDimensionalArray), see [OneDimensionalArray](pageonedimensionalarray.xhtml).

As with the [OneDimensionalArray](db.xhtml?OneDimensionalArray) domain, a

[Vector](db.xhtml?Vector) can be created by calling the operation [new](dbopnew.xhtml), its components can be accessed by calling the operations [elt](dbopelt.xhtml) and [qelt](dbopqelt.xhtml), and its components can be reset by calling the operations [setelt](dbopsetelt.xhtml) and [setelt!](dbopseteltbang.xhtml). This creates a vector of integers of length 5 all of whose components are 12.

```

 <input type="submit" id="p1" class="subbut"
 onclick="makeRequest('p1');"
 value="u:VECTOR INT:=new(5,12)" />
 <div id="ansp1"><div></div></div>

```

This is how you create a vector from a list of its components.

```

 <input type="submit" id="p2" class="subbut"
 onclick="makeRequest('p2');"
 value="v:VECTOR INT:=vector([1,2,3,4,5])" />
 <div id="ansp2"><div></div></div>

```

Indexing for vectors begins at 1. The last element has index equal to the length of the vector, which is computed by

```
#.
```

```

 <input type="submit" id="p3" class="subbut"
 onclick="handleFree(['p2','p3']);"
 value="#(v)" />
 <div id="ansp3"><div></div></div>

```

This is the standard way to use `<a href="dbopelt.xhtml">elt</a>` to extract an element.

```

 <input type="submit" id="p4" class="subbut"
 onclick="handleFree(['p2','p4']);"
 value="v.2" />
 <div id="ansp4"><div></div></div>

```

This is the standard way to use `setelt` to change an element. It is the same as if you had typed `setelt(v,3,99)`.

```

 <input type="submit" id="p5" class="subbut"
 onclick="handleFree(['p2','p5']);"
 value="v.3:=99" />
 <div id="ansp5"><div></div></div>

```

Now look at `v` to see the change. You can use

```
qelt and
qsetelt! (instead of
elt and
setelt, respectively) but only when you
know that the index is within the valid range.
```

```

 <input type="submit" id="p6" class="subbut"
 onclick="handleFree(['p2','p6']);"
 value="v" />
 <div id="ansp6"><div></div></div>

When the components belong to a
Ring,
Axiom provides arithmetic operations for
Vector. These include left and right
scalar multiplication.

 <input type="submit" id="p7" class="subbut"
 onclick="handleFree(['p2','p7']);"
 value="5*v" />
 <div id="ansp7"><div></div></div>

 <input type="submit" id="p8" class="subbut"
 onclick="handleFree(['p2','p8']);"
 value="v*7" />
 <div id="ansp8"><div></div></div>

 <input type="submit" id="p9" class="subbut"
 onclick="makeRequest('p9');"
 value="w:VECTOR INT:=vector([2,3,4,5,6])" />
 <div id="ansp9"><div></div></div>

Addition and subtraction are also available

 <input type="submit" id="p10" class="subbut"
 onclick="handleFree(['p2','p9','p10']);"
 value="v+w" />
 <div id="ansp10"><div></div></div>

Of course, when adding or subtracting, the two vectors must have the
same length or an error message is displayed.

```

```

<input type="submit" id="p11" class="subbut"
 onclick="handleFree(['p9','p11']);"
 value="v-w" />
<div id="ansp11"><div></div></div>

```

For more information about other aggregate domains, see

```

List,
Matrix,
OneDimensionalArray.
Set,
Table, and
TwoDimensionalArray.

```

Issue the system command

```

 <input type="submit" id="p12" class="subbut"
 onclick="showcall('p12');"
 value=")show Vector"/>
 <div id="ansp12"><div></div></div>

```

to display the full list of operations defined by

```

Vector.

```

*<page foot>*

## 1.9.378 lin1darrays.xhtml

```

<lin1darrays.xhtml>≡
 <standard head>
 <script type="text/javascript">
 <handlefreevars>
 <axiom talker>
 </script>
 </head>
 <body>
 <page head>
 <div align="center">One Dimensional Array</div>
 <hr/>

```

The `<a href="db.xhtml?OneDimensionalArray">OneDimensionalArray</a>` is used for storing data in a one-dimensional indexed data structure. Such an array is a homogeneous data structure in that all the entries of the array must belong to the same Axiom domain. Each array has a fixed length specified by the user and arrays are not extensible. The indexing of one-dimensional arrays is one-based. This means that the "first" element of an array is given the index 1. See also

`<a href="db.xhtml?Vector">Vector</a>` and  
`<a href="db.xhtml?FlexibleArray">FlexibleArray</a>`. To create a one-dimensional array, apply the operation  
`<a href="dboponedimensionalarray.xhtml">oneDimensionalArray</a>` to a list.

```

 <input type="submit" id="p1" class="subbut"
 onclick="makeRequest('p1');"
 value="oneDimensionalArray [i^2 for i in 1..10]" />
 <div id="ansp1"><div></div></div>

```

Another approach is to first create a, a one-dimensional array of 10 0's.

`<a href="db.xhtml?OneDimensionalArray">OneDimensionalArray</a>` has a convenient abbreviation

`<a href="db.xhtml?OneDimensionalArray">ARRAY1</a>`.

```

 <input type="submit" id="p2" class="subbut"
 onclick="makeRequest('p2');"
 value="a:ARRAY1 INT := new(10,0)" />
 <div id="ansp2"><div></div></div>

```

Set each *i*th element to *i*, then display the result.

```

```

```

 <input type="submit" id="p3" class="subbut"
 onclick="handleFree(['p2','p3']);"
 value="for i in 1..10 repeat a.i:=i ; a" />
 <div id="ansp3"><div></div></div>

```

Square each element by mapping the function  $i \mapsto i^2$  onto each element.

```

 <input type="submit" id="p4" class="subbut"
 onclick="handleFree(['p1','p2','p4']);"
 value="map!(i->i^2,a); a" />
 <div id="ansp4"><div></div></div>

```

Reverse the elements in place.

```

 <input type="submit" id="p5" class="subbut"
 onclick="handleFree(['p1','p2','p3','p4','p5']);"
 value="reverse! a" />
 <div id="ansp5"><div></div></div>

```

Swap the 4th and 5th element.

```

 <input type="submit" id="p6" class="subbut"
 onclick="handleFree(['p1','p2','p3','p4','p5','p6']);"
 value="swap!(a,4,5); a" />
 <div id="ansp6"><div></div></div>

```

Sort the elements in place.

```

 <input type="submit" id="p7" class="subbut"
 onclick="handleFree(['p1','p2','p3','p4','p5','p6','p7']);"
 value="sort! a" />
 <div id="ansp7"><div></div></div>

```

Create a new one-dimensional array b containing the last 5 elements of a.

```

```

```

 <input type="submit" id="p8" class="subbut"
 onclick="handleFree(['p1','p2','p3','p4','p5','p6','p7','p8']);"
 value="b:=a(6..10)" />
 <div id="ansp8"><div></div></div>

Replace the first 5 elements of a with those of b.

 <input type="submit" id="p9" class="subbut"
 onclick="handleFree(['p1','p2','p3','p4','p5','p6','p7','p8','p9']);"
 value="copyInto!(a,b,1)" />
 <div id="ansp9"><div></div></div>

<page foot>

```

### 1.9.379 lin2darrays.xhtml

```

<lin2darrays.xhtml>≡
 <standard head>
 <script type="text/javascript">
 <handlefreevars>
 <axiom talker>
 </script>
 </head>
 <body>
 <page head>
 <div align="center">Two Dimensional Array</div>
 <hr/>

```

The `<a href="db.xhtml?TwoDimensionalArray">TwoDimensionalArray</a>` is used for storing data in a two-dimensional data structure indexed by row and by column. Such an array is a homogeneous data structure in that all the entries of the array must belong to the same Axiom domain (although see the `<a href="axbook/section-2.6.xhtml">Any</a>` domain). Each array has a fixed number of rows and columns specified by the user and arrays are not extensible. In Axiom, the indexing of two-dimensional arrays is one-based. This means that both the "first" row of an array and the "first" column of an array are given the index 1. Thus, the entry in the upper left corner of an array is in position (1,1).

The operation `<a href="dbopnew.xhtml">new</a>` creates an array with a specified number of rows and columns and fills the components of that array with a specified entry. The arguments of this operation specify the number of rows, the number of columns, and the entry. This creates a five-by-four array of integers, all of which are zero.

```

 <input type="submit" id="p1" class="subbut"
 onclick="makeRequest('p1');"
 value="arr:ARRAY2 INT:=new(5,4,0)" />
 <div id="ansp1"><div></div></div>

```

The entries of this array can be set to other integers using the operation `<a href="dbopsetelt.xhtml">setelt</a>`.

Issue this to set the element in the upper left corner of this array to 17.

```

 <input type="submit" id="p2" class="subbut"
 onclick="handleFree(['p1','p2']);"
 value="setelt(arr,1,1,17)" />

```

```

 <div id="ansp2"><div></div></div>

Now the first element of the array is 17.

 <input type="submit" id="p3" class="subbut"
 onclick="handleFree(['p1','p2','p3']);"
 value="arr" />
 <div id="ansp3"><div></div></div>

```

Likewise, elements of an array are extracted using the operation  
[elt](dbopelt.xhtml).

```

 <input type="submit" id="p4" class="subbut"
 onclick="handleFree(['p1','p2','p4']);"
 value="elt(arr,1,1)" />
 <div id="ansp4"><div></div></div>

```

Another way to use these two operations is as follows. This sets the  
 element in position (3,2) of the array to 15.

```

 <input type="submit" id="p5" class="subbut"
 onclick="handleFree(['p1','p2','p5']);"
 value="arr(3,2):=15" />
 <div id="ansp5"><div></div></div>

```

This extracts the element in position (3,2) of the array.

```

 <input type="submit" id="p6" class="subbut"
 onclick="handleFree(['p1','p2','p5','p6']);"
 value="arr(3,2)" />
 <div id="ansp6"><div></div></div>

```

The operations [elt](dbopelt.xhtml) and [setelt](dbopsetelt.xhtml) come equipped with an error check which  
 verifies that the indices are in the proper ranges. For example, the  
 above array has five rows and four columns, so if you ask for the entry  
 in position (6,2) with `arr(6,2)` Axiom displays an error message. If there

is no need for an error check, you can call the operations  
[qelt](dbopqelt.xhtml) and  
[qsetelt!](dbopqseteltbang.xhtml) which provide the same  
 functionality but without the error check. Typically, these operations  
 are called in well-tested programs.

The operations [row](dboprow.xhtml) and  
[column](dbopcolumn.xhtml) extract rows and columns,  
 respectively, and return objects of  
[OneDimensionalArray](db.xhtml?OneDimensionalArray) with the  
 same underlying element type.

```

 <input type="submit" id="p7" class="subbut"
 onclick="handleFree(['p1','p2','p5','p7']);"
 value="row(arr,1)" />
 <div id="ansp7"><div></div></div>

 <input type="submit" id="p8" class="subbut"
 onclick="handleFree(['p1','p2','p5','p8']);"
 value="column(arr,1)" />
 <div id="ansp8"><div></div></div>

```

You can determine the dimensions of an array by calling the operations  
[nrows](dbopnrows.xhtml) and [ncols](dbopncols.xhtml),  
 which return the number of rows and columns, respectively.

```

 <input type="submit" id="p9" class="subbut"
 onclick="handleFree(['p1','p9']);"
 value="nrows(arr)" />
 <div id="ansp9"><div></div></div>

 <input type="submit" id="p10" class="subbut"
 onclick="handleFree(['p1','p10']);"
 value="ncols(arr)" />
 <div id="ansp10"><div></div></div>

```

To apply an operation to every element of an array, use  
[map](dbopmap.xhtml). This creates a new array. This  
 expression negates every element.

```

 <input type="submit" id="p11" class="subbut"
 onclick="handleFree(['p1','p2','p5','p11']);"
 value="map(-,arr)" />
 <div id="ansp11"><div></div></div>

```

This creates an array where all the elements are doubled.

```

 <input type="submit" id="p12" class="subbut"
 onclick="handleFree(['p1','p2','p5','p12']);"
 value="map((x+>x+x),arr)" />
 <div id="ansp12"><div></div></div>

```

To change the array destructively, use

`<a href="dbopmapbang.xhtml">map!</a>` instead of  
`<a href="dbopmap.xhtml">map</a>`. If you need to make a copy of any array,  
 use `<a href="dbopcopy.xhtml">copy</a>`.

```

 <input type="submit" id="p13" class="subbut"
 onclick="handleFree(['p1','p2','p5','p13']);"
 value="arrc:=copy(arr)" />
 <div id="ansp13"><div></div></div>

 <input type="submit" id="p14" class="subbut"
 onclick="handleFree(['p1','p2','p5','p13','p14']);"
 value="map!(-,arrc)" />
 <div id="ansp14"><div></div></div>

 <input type="submit" id="p15" class="subbut"
 onclick="handleFree(['p1','p2','p5','p13','p14','p15']);"
 value="arrc" />
 <div id="ansp15"><div></div></div>

 <input type="submit" id="p16" class="subbut"
 onclick="handleFree(['p1','p2','p5','p16']);"
 value="arrc:=copy(arr)" />
 <div id="ansp16"><div></div></div>

```

```

```

Use [member?](dbopmemberq.xhtml) to see if a given element is in an array.

```

```

```

```

```
<input type="submit" id="p17" class="subbut"
 onclick="handleFree(['p1','p2','p5','p17']);"
 value="member?(17,arr)" />
```

```
<div id="ansp17"><div></div></div>
```

```

```

```

```

```
<input type="submit" id="p18" class="subbut"
 onclick="handleFree(['p1','p2','p5','p18']);"
 value="member?(10317,arr)" />
```

```
<div id="ansp18"><div></div></div>
```

```

```

```

```

To see how many times an element appears in an array, use

[count](dbopcount.xhtml).

```

```

```

```

```
<input type="submit" id="p19" class="subbut"
 onclick="handleFree(['p1','p2','p5','p19']);"
 value="count(17,arr)" />
```

```
<div id="ansp19"><div></div></div>
```

```

```

```

```

```
<input type="submit" id="p20" class="subbut"
 onclick="handleFree(['p1','p2','p5','p20']);"
 value="count(0,arr)" />
```

```
<div id="ansp20"><div></div></div>
```

```

```

```

```

## 1.9.477 numbasicfunctions.xhtml

```

<numbasicfunctions.xhtml>≡
 <standard head>
 <script type="text/javascript">
 <handlefreevars>
 <axiom talker>
 </script>
 </head>
 <body>
 <page head>
 <div align="center">Basic Functions</div>
 <hr/>

```

The size of an integer in Axiom is only limited by the amount of computer storage you have available. The usual arithmetic operations are available.

```

 <input type="submit" id="p1" class="subbut"
 onclick="makeRequest('p1');"
 value="2^(5678-4856+2*17)" />
 <div id="ansp1"><div></div></div>

```

There are a number of ways of working with the sign of an integer. Let's use the x as an example.

```

 <input type="submit" id="p2" class="subbut"
 onclick="makeRequest('p2');"
 value="x:=-101" />
 <div id="ansp2"><div></div></div>

```

First of all, there is the absolute value function.

```

 <input type="submit" id="p3" class="subbut"
 onclick="handleFree(['p2','p3']);"
 value="abs(x)" />
 <div id="ansp3"><div></div></div>

```

The <a href="dbopsign.xhtml">sign</a> operation returns -1 if its argument is negative, 0 if zero and 1 if positive.

```

```

```

<input type="submit" id="p4" class="subbut"
 onclick="handleFree(['p2','p4']);"
 value="sign(x)" />
<div id="ansp4"><div></div></div>

```

You can determine if an integer is negative in several other ways.

```

 <input type="submit" id="p5" class="subbut"
 onclick="handleFree(['p2','p5']);"
 value="x < 0" />
 <div id="ansp5"><div></div></div>

 <input type="submit" id="p6" class="subbut"
 onclick="handleFree(['p2','p6']);"
 value="x <= -1" />
 <div id="ansp6"><div></div></div>

 <input type="submit" id="p7" class="subbut"
 onclick="handleFree(['p2','p7']);"
 value="negative?(x)" />
 <div id="ansp7"><div></div></div>

```

Similarly, you can find out if it is positive.

```

 <input type="submit" id="p8" class="subbut"
 onclick="handleFree(['p2','p8']);"
 value="x > 0" />
 <div id="ansp8"><div></div></div>

 <input type="submit" id="p9" class="subbut"
 onclick="handleFree(['p2','p9']);"
 value="x >= 1" />
 <div id="ansp9"><div></div></div>

 <input type="submit" id="p10" class="subbut"
 onclick="handleFree(['p2','p10']);"
 value="positive?(x)" />
 <div id="ansp10"><div></div></div>

```

```

```

```

```

This is the recommended way of determining whether an integer is zero.

```

```

```

```

```
<input type="submit" id="p11" class="subbut"
 onclick="handleFree(['p1','p11']);"
 value="zero?(x)" />
```

```
<div id="ansp11"><div></div></div>
```

```

```

```

```

```
<hr/>
```

Use the `<a href="dbopzeroq.xhtml">zero?</a>` whenever you are testing any mathematical object for equality with zero. This is usually more efficient than using `<a href="dbopequal.xhtml">=</a>` (think of matrices: it is easier to tell if a matrix is zero by just checking term by term than constructing another "zero" matrix and comparing the two matrices term by term) and also avoids the problem that `<a href="dbopequal.xhtml">=</a>` is usually used for creating equations.

```
<hr/>
```

This is the recommended way of determining whether an integer is equal to one.

```

```

```

```

```
<input type="submit" id="p12" class="subbut"
 onclick="handleFree(['p2','p12']);"
 value="one?(x)" />
```

```
<div id="ansp12"><div></div></div>
```

```

```

```

```

This syntax is used to test equality using `<a href="dbopequal.xhtml">=</a>`. It says that you want a `<a href="db.xhtml?Boolean">Boolean</a>` (true or false) answer rather than an equation.

```

```

```

```

```
<input type="submit" id="p13" class="subbut"
 onclick="handleFree(['p2','p13']);"
 value="(x=-101)@Boolean" />
```

```
<div id="ansp13"><div></div></div>
```

```

```

```

```

The operations `<a href="dbopoddq.xhtml">odd?</a>` and `<a href="dbopevenq.xhtml">even?</a>` determine whether an integer is odd or even, respectively. They each return a `<a href="db.xhtml?Boolean">Boolean</a>` object.

```

```

```

 <input type="submit" id="p14" class="subbut"
 onclick="handleFree(['p2','p14']);"
 value="odd?(x)" />
 <div id="ansp14"><div></div></div>

 <input type="submit" id="p15" class="subbut"
 onclick="handleFree(['p2','p15']);"
 value="even?(x)" />
 <div id="ansp15"><div></div></div>

```

The operation [gcd](dbopgcd.xhtml) computes the greatest common divisor of two integers.

```

 <input type="submit" id="p16" class="subbut"
 onclick="makeRequest('p16');"
 value="gcd(56788,43688)" />
 <div id="ansp16"><div></div></div>

```

The operation [lcm](dboplcm.xhtml) computes their least common multiple.

```

 <input type="submit" id="p17" class="subbut"
 onclick="makeRequest('p17');"
 value="lcm(56788,43688)" />
 <div id="ansp17"><div></div></div>

```

To determine the maximum of two integers, use [max](dbopmax.xhtml).

```

 <input type="submit" id="p18" class="subbut"
 onclick="makeRequest('p18');"
 value="max(678,567)" />
 <div id="ansp18"><div></div></div>

```

To determine the minimum, use [min](dbopmin.xhtml).

```

 <input type="submit" id="p20" class="subbut"

```

```

 onclick="makeRequest('p20');"
 value="min(678,567)" />
 <div id="ansp20"><div></div></div>

```

The `<a href="dbopreduce.xhtml">reduce</a>` operation is used to extend binary operations to more than two arguments. For example, you can use `<a href="dbopreduce.xhtml">reduce</a>` to find the maximum integer in a list or compute the least common multiple of all integers in a list.

```

 <input type="submit" id="p21" class="subbut"
 onclick="makeRequest('p21');"
 value="reduce(max,[2,45,-89,78,100,-45])" />
 <div id="ansp21"><div></div></div>

 <input type="submit" id="p22" class="subbut"
 onclick="makeRequest('p22');"
 value="reduce(min,[2,45,-89,78,100,-45])" />
 <div id="ansp22"><div></div></div>

 <input type="submit" id="p23" class="subbut"
 onclick="makeRequest('p23');"
 value="reduce(gcd,[2,45,-89,78,100,-45])" />
 <div id="ansp23"><div></div></div>

 <input type="submit" id="p24" class="subbut"
 onclick="makeRequest('p24');"
 value="reduce(lcm,[2,45,-89,78,100,-45])" />
 <div id="ansp24"><div></div></div>

```

The infix operator `/"` is not used to compute the quotient of integers.

Rather, it is used to create rational numbers as described in

`<a href="numintegerfractions.xhtml">Fractions</a>`.

```

 <input type="submit" id="p25" class="subbut"
 onclick="makeRequest('p25');"
 value="13/4" />
 <div id="ansp25"><div></div></div>

```

The infix operator `<a href="dbopquo.xhtml">quo</a>` computes the integer quotient.

```

 <input type="submit" id="p26" class="subbut"
 onclick="makeRequest('p26');"
 value="13 quo 4" />
 <div id="ansp26"><div></div></div>

```

The infix operation `<a href="dboprem.xhtml">rem</a>` computes the integer remainder.

```

 <input type="submit" id="p27" class="subbut"
 onclick="makeRequest('p27');"
 value="13 rem 4" />
 <div id="ansp27"><div></div></div>

```

One integer is evenly divisible by another if the remainder is zero.

The operation `<a href="dbopexquo.xhtml">exquo</a>` can also be used. See `<a href="axbook/section-2.5.xhtml">Unions</a>` for an example.

```

 <input type="submit" id="p28" class="subbut"
 onclick="makeRequest('p28');"
 value="zero?(167604736446952 rem 2003644)" />
 <div id="ansp28"><div></div></div>

```

The operation `<a href="dbopdivide.xhtml">divide</a>` returns a record of the quotient and remainder and thus is more efficient when both are needed.

```

 <input type="submit" id="p29" class="subbut"
 onclick="makeRequest('p29');"
 value="d:=divide(13,4)" />
 <div id="ansp29"><div></div></div>

 <input type="submit" id="p30" class="subbut"
 onclick="handleFree(['p29','p30']);"
 value="d.quotient" />
 <div id="ansp30"><div></div></div>

```

```

Records are discussed in detail in
Records.

 <input type="submit" id="p31" class="subbut"
 onclick="handleFree(['p29','p31']);"
 value="d.remainder" />
 <div id="ansp31"><div></div></div>

<page foot>
```

### 1.9.479 numcardinalnumbers.xhtml

*(numcardinalnumbers.xhtml)*≡

```

<standard head>
 <script type="text/javascript">
 <handlefreevars>
 <axiom talker>
 </script>
</head>
<body onload="resetvars();">
 <page head>
 <div align="center">Cardinal Numbers</div>
 <hr/>

```

The `<a href="dbopcardinalnumber.xhtml">CardinalNumber</a>` can be used for values indicating the cardinality of sets, both finite and infinite. For example, the `<a href="dbopdimension.xhtml">dimension</a>` operation in the category `<a href="dbopvectorspace.xhtml">VectorSpace</a>` returns a cardinal number.

The non-negative integers have a natural construction as cardinals

```

<pre>
0={ }, 1={0}, 2={0,1}, ..., n={i | 0 ≤ i ≤ n}
</pre>

```

The fact that 0 acts as a zero for the multiplication of cardinals is equivalent to the axiom of choice.

Cardinal numbers can be created by conversion from non-negative integers.

```

 <input type="submit" id="p1" class="subbut" onclick="makeRequest('p1');"
 value="c0:=0::CardinalNumber" />
 <div id="ansp1"><div></div></div>

 <input type="submit" id="p2" class="subbut" onclick="makeRequest('p2');"
 value="c1:=1::CardinalNumber" />
 <div id="ansp2"><div></div></div>

 <input type="submit" id="p3" class="subbut" onclick="makeRequest('p3');"
 value="c2:=2::CardinalNumber" />
 <div id="ansp3"><div></div></div>

 <input type="submit" id="p4" class="subbut" onclick="makeRequest('p4');"
 value="c3:=3::CardinalNumber" />

```

```

 <div id="ansp4"><div></div></div>

```

The can also be obtained as the named cardinal  $\text{Aleph}(n)$

```

 <input type="submit" id="p5" class="subbut" onclick="makeRequest('p5');"
 value="A0:=Aleph 0" />
 <div id="ansp5"><div></div></div>

 <input type="submit" id="p6" class="subbut" onclick="makeRequest('p6');"
 value="A1:=Aleph 1" />
 <div id="ansp6"><div></div></div>

```

The [finite?](dbopfiniteq.xhtml) operation tests whether a value is a finite cardinal, that is, a non-negative integer.

```

 <input type="submit" id="p7" class="subbut"
 onclick="handleFree(['p3','p7']);"
 value="finite? c2" />
 <div id="ansp7"><div></div></div>

 <input type="submit" id="p8" class="subbut"
 onclick="handleFree(['p5','p8']);"
 value="finite? A0" />
 <div id="ansp8"><div></div></div>

```

Similarly, the [countable?](dbopcountableq.xhtml) operation determines whether a value is a countable cardinal, that is, finite or  $\text{Aleph}(0)$ .

```

 <input type="submit" id="p9" class="subbut"
 onclick="handleFree(['p3','p9']);"
 value="countable? c2" />
 <div id="ansp9"><div></div></div>

 <input type="submit" id="p10" class="subbut"
 onclick="handleFree(['p5','p10']);"
 value="countable? A0" />

```

```

 <div id="ansp10"><div></div></div>

 <input type="submit" id="p11" class="subbut"
 onclick="handleFree(['p6','p11']);"
 value="countable? A1" />
 <div id="ansp11"><div></div></div>

Arithmetic operations are defined on cardinal numbers as follows:
<table>
<tr>
<td>
 $x+y = \#(X+Y)$
</td>
<td>
 cardinality of the disjoint union
 </td>
</tr>
<tr>
<td>
 $x-y = \#(X-Y)$
</td>
<td>
 cardinality of the relative complement
 </td>
</tr>
<tr>
<td>
 $x*y = \#(X*Y)$
</td>
<td>
 cardinality of the Cartesian product
 </td>
</tr>
<tr>
<td>
 $x**y = \#(X**Y)$
</td>
<td>
 cardinality of the set of maps from Y to X
 </td>
</tr>
</table>
Here are some arithmetic examples:

```

```

 <input type="submit" id="p12" class="subbut"
 onclick="handleFree(['p3','p6','p12']);"
 value="[c2+c2,c1+A1]" />
 <div id="ansp12"><div></div></div>

 <input type="submit" id="p13" class="subbut"
 onclick="handleFree(['p1','p2','p3','p5','p6','p13']);"
 value="[c0*c2,c1*c2,c2*c2,c0*A1,c1*A1,c2*A1,A0*A1]" />
 <div id="ansp13"><div></div></div>

 <input type="submit" id="p14" class="subbut"
 onclick="handleFree(['p1','p2','p3','p6','p14']);"
 value="[c2**c0,c2**c1,c2**c2,A1**c0,A1**c1,A1**c2]" />
 <div id="ansp14"><div></div></div>

```

Subtraction is a partial operation; it is not defined when subtracting a larger cardinal from a smaller one, nor when subtracting two equal infinite cardinals.

```

 <input type="submit" id="p15" class="subbut"
 onclick="handleFree(['p2','p3','p4','p5','p6','p15']);"
 value="[c2-c1,c2-c2,c2-c3,A1-c2,A1-A0,A1-A1]" />
 <div id="ansp15"><div></div></div>

```

The generalized continuum hypothesis asserts that

```

<pre>
2**Aleph i = Aleph(i+1)
</pre>

```

and is independent of the axioms of set theory. (Goedel, The consistency of the continuum hypothesis, Ann. Math. Studies, Princeton Univ. Press, 1940) The [CardinalNumber](dbopcardinalnumber.xhtml) domain provides an operation to assert whether the hypothesis is to be assumed.

```

 <input type="submit" id="p16" class="subbut"
 onclick="makeRequest('p16');"
 value="generalizedContinuumHypothesisAssumed true" />
 <div id="ansp16"><div></div></div>

```

When the generalized continuum hypothesis is assumed, exponentiation to a transfinite power is allowed.

```

 <input type="submit" id="p17" class="subbut"
 onclick="handleFree(['p1','p2','p3','p5','p6','p17']);"
 value="[c0**A0,c1**A0,c2**A0,A0**A0,A0**A1,A1**A0,A1**A1]" />
 <div id="ansp17"><div></div></div>

```

Three commonly encountered cardinal numbers are

```
<pre>
 a = #Z countable infinity
 c = #R the continuum
 f = #{g|g: [0,1]->R}
</pre>
```

In this domain, these values are obtained under the generalized continuum hypothesis in this way:

```

 <input type="submit" id="p18" class="subbut"
 onclick="makeRequest('p18');"
 value="a:=Aleph 0" />
 <div id="ansp18"><div></div></div>

 <input type="submit" id="p19" class="subbut"
 onclick="handleFree(['p18','p19']);"
 value="c:=2**a" />
 <div id="ansp19"><div></div></div>

 <input type="submit" id="p20" class="subbut"
 onclick="handleFree(['p18','p19','p20']);"
 value="f:=2**c" />
 <div id="ansp20"><div></div></div>

```

*<page foot>*

## 1.9.480 numcomplexnumbers.xhtml

```

<numcomplexnumbers.xhtml>≡
 <standard head>
 <script type="text/javascript">
 <handlefreevars>
 <axiom talker>
 </script>
 </head>
 <body onload="resetvars();">
 <page head>
 <div align="center">Complex Numbers</div>
 <hr/>
 The Complex constructor implements
 complex objects over a commutative ring R. Typically, the ring R is
 Integer,
 Fraction Integer,
 Float,
 DoubleFloat,
 R can also be a symbolic type, like
 Polynomial Integer.
 For more information about the numerical and graphical aspects of
 complex numbers, see
 Numeric Functions
 in section 8.1.

 Complex objects are created by the
 complex operation

 <input type="submit" id="p1" class="subbut" onclick="makeRequest('p1');"
 value="a:=complex(4/3,5/2)" />
 <div id="ansp1"><div></div></div>

 <input type="submit" id="p2" class="subbut" onclick="makeRequest('p2');"
 value="b:=complex(4/3,-5/2)" />
 <div id="ansp2"><div></div></div>

 The standard arithmetic operations are available.

 <input type="submit" id="p3" class="subbut"
 onclick="handleFree(['p1','p2','p3']);"
 value="a+b" />

```

```

 <div id="ansp3"><div></div></div>

 <input type="submit" id="p4" class="subbut"
 onclick="handleFree(['p1','p2','p4']);"
 value="a-b" />
 <div id="ansp4"><div></div></div>

 <input type="submit" id="p5" class="subbut"
 onclick="handleFree(['p1','p2','p5']);"
 value="a*b" />
 <div id="ansp5"><div></div></div>

```

If  $R$  is a field, you can also divide the complex objects.

```

 <input type="submit" id="p6" class="subbut"
 onclick="handleFree(['p1','p2','p6']);"
 value="a/b" />
 <div id="ansp6"><div></div></div>

```

Use a conversion

(see <axbook/section-2.7.xhtml> Conversion in section 2.7) to view the last object as a fraction of complex integers.

```

 <input type="submit" id="p7" class="subbut"
 onclick="handleFree(['p1','p2','p6','p7']);"
 value="%::Fraction Complex Integer" />
 <div id="ansp7"><div></div></div>

```

The predefined macro `<tt>%i</tt>` is defined to be `complex(0,1)`.

```

 <input type="submit" id="p8" class="subbut"
 onclick="makeRequest('p8');"
 value="3.4+6.7*i" />
 <div id="ansp8"><div></div></div>

```

You can also compute the

[conjugate](dbcomplexconjugate.xhtml) and  
[norm](dbcomplexnorm.xhtml) of a complex number.

```

 <input type="submit" id="p9" class="subbut"
 onclick="handleFree(['p1','p9']);"
 value="conjugate a" />
 <div id="ansp9"><div></div></div>

 <input type="submit" id="p10" class="subbut"
 onclick="handleFree(['p1','p10']);"
 value="norm a" />
 <div id="ansp10"><div></div></div>

```

The [real](dbcomplexreal.xhtml) and  
[imag](dbcompleximag.xhtml) operations are provided to  
extract the real and imaginary parts, respectively.

```

 <input type="submit" id="p11" class="subbut"
 onclick="handleFree(['p1','p11']);"
 value="real a" />
 <div id="ansp11"><div></div></div>

 <input type="submit" id="p12" class="subbut"
 onclick="handleFree(['p1','p12']);"
 value="imag a" />
 <div id="ansp12"><div></div></div>

```

The domain

[Complex Integer](dbcomplexinteger.xhtml)  
is also called the Gaussian integers. If  $R$  is the integers (or, more  
generally, a  
[Euclidean Domain](db.xhtml?EuclideanDomain)),  
you can compute greatest common divisors.

```

 <input type="submit" id="p13" class="subbut"
 onclick="makeRequest('p13');"
 value="gcd(12-12*i,31+27*i)" />
 <div id="ansp13"><div></div></div>

```

```

You can also compute least common multiples

 <input type="submit" id="p14" class="subbut"
 onclick="makeRequest('p14');"
 value="lcm(13-13*%i,31+27*%i)" />
 <div id="ansp14"><div></div></div>

You can factor Gaussian integers.

 <input type="submit" id="p15" class="subbut"
 onclick="makeRequest('p15');"
 value="factor(13-13*%i)" />
 <div id="ansp15"><div></div></div>

 <input type="submit" id="p16" class="subbut"
 onclick="makeRequest('p16');"
 value="factor complex(2,0)" />
 <div id="ansp16"><div></div></div>

<page foot>

```

## 1.9.481 numcontinuedfractions.xhtml

*(numcontinuedfractions.xhtml)*≡

```

<standard head>
 <script type="text/javascript">
 <handlefreevars>
 <axiom talker>
 </script>
</head>
<body onload="resetvars();">
 <page head>
 <div align="center">Continued Fractions</div>
 <hr/>

```

Continued fractions have been a fascinating and useful tool in mathematics for well over three hundred years. Axiom implements continued fractions for fractions of any Euclidean domain. In practice, this usually means rational numbers. In this section we demonstrate some of the operations available for manipulating both finite and infinite continued fractions. It may be helpful if you review [Stream](db.xhtml?Stream) to remind yourself of some of the operations with streams.

The [ContinuedFraction](db.xhtml?ContinuedFraction) domain is a field and therefore you can add, subtract, multiply, and divide the fractions. The [continuedFraction](dbopcontinuedfraction.xhtml) operation converts its fractional argument to a continued fraction.

```

 <input type="submit" id="p1" class="subbut" onclick="makeRequest('p1');"
 value="c:=continuedFraction(314159/100000)" />
 <div id="ansp1"><div></div></div>

```

This display is the compact form of the bulkier

```
<pre>
```

```

3 +

7 +

15 +

1 +

25 +

```

$$1 + \frac{1}{7 + \frac{1}{-4}}$$

</pre>

You can write any rational number in a similar form. The fraction will be finite and you can always take the "numerators" to be 1. That is, any rational number can be written as a simple, finite continued fraction of the form

<pre>

$$a(1) + \frac{1}{a(2) + \frac{1}{a(3) + \frac{1}{\ddots \frac{1}{a(n-1) + \frac{1}{a(n)}}}}$$

</pre>

The  $a(i)$  are called partial quotients and the operation

[partialQuotients](dboppartialquotients.xhtml) creates a stream of them.

<ul>

<li>

```
<input type="submit" id="p2" class="subbut"
 onclick="handleFree(['p1','p2']);"
 value="partialQuotients c" />
<div id="ansp2"><div></div></div>
```

</li>

</ul>

By considering more and more of the fraction, you get the

[convergents](dbopconvergents.xhtml). For example, the first convergent is  $a(1)$ , the second is  $a(1)+1/a(2)$  and so on.

<ul>

<li>

```
<input type="submit" id="p3" class="subbut"
 onclick="handleFree(['p1','p3']);"
 value="convergents c" />
<div id="ansp3"><div></div></div>
```

```

```

Since this is a finite continued fraction, the last convergent is the original rational number, in reduced form. The result of [approximants](dbopapproximants.xhtml) is always an infinite stream, though it may just repeat the "last" value.

```

 <input type="submit" id="p4" class="subbut"
 onclick="handleFree(['p1','p4']);"
 value="approximants c" />
 <div id="ansp4"><div></div></div>

```

Inverting c only changes the partial quotients of its fraction by inserting a 0 at the beginning of the list.

```

 <input type="submit" id="p5" class="subbut"
 onclick="handleFree(['p1','p5']);"
 value="pq:=partialQuotients(1/c)" />
 <div id="ansp5"><div></div></div>

```

Do this to recover the original continued fraction from this list of partial quotients. The three argument form of the [continuedFraction](dbopcontinuedfraction.xhtml) operation takes an element which is the whole part of the fraction, a stream of elements which are the denominators of the fraction.

```

 <input type="submit" id="p6" class="subbut"
 onclick="handleFree(['p1','p5','p6']);"
 value="continuedFraction(first pq,repeating [1],rest pq)" />
 <div id="ansp6"><div></div></div>

```

The streams need not be finite for [continuedFraction](dbopcontinuedfraction.xhtml). Can you guess which irrational number has the following continued fraction? See the end of this section for the answer.

```

 <input type="submit" id="p7" class="subbut" onclick="makeRequest('p7');"
 value="z:=continuedFraction(3,repeating [1],repeating [3,6])" />
 <div id="ansp7"><div></div></div>

```

</li>  
 </ul>  
 In 1737 Euler discovered the infinite continued fraction expansion

```
<pre>
e - 1 1
----- = -----
p 2 + -----
 6 + -----
 10 + -----
 14 + ...

```

</pre>  
 We use this expansion to compute rational and floating point approximations of e. (For this and other interesting expansions, see C. D. Olds, Continued Fractions, New Mathematical Library, Random House, New York, 1963 pp.134-139).

By looking at the above expansion, we see that the whole part is 0 and the numerators are all equal to 1. This constructs the stream of denominators.

```

 <input type="submit" id="p8" class="subbut" onclick="makeRequest('p8');"
 value="dens:Stream Integer:=cons(1,generate((x+>x+4),6))" />
 <div id="ansp8"><div></div></div>

```

Therefore this is the continued fraction expansion for (e-1)/2.

```

 <input type="submit" id="p9" class="subbut"
 onclick="handleFree(['p8','p9']);"
 value="cf:=continuedFraction(0,repeating [1],dens)" />
 <div id="ansp9"><div></div></div>

```

These are the rational number convergents.

```

 <input type="submit" id="p10" class="subbut"
 onclick="handleFree(['p8','p9','p10']);"
 value="ccf:=convergents cf" />
 <div id="ansp10"><div></div></div>

```

</ul>

You can get rational convergents for e by multiplying by 2 and adding 1.

<ul>

<li>

```
<input type="submit" id="p11" class="subbut"
 onclick="handleFree(['p8','p9','p10','p11']);"
 value="eConvergents:=[2*e+1 for e in ccfl]" />
<div id="ansp11"><div></div></div>
```

</li>

</ul>

You can also compute the floating point approximations to these convergents.

<ul>

<li>

```
<input type="submit" id="p12" class="subbut"
 onclick="handleFree(['p8','p9','p10','p11','p12']);"
 value="eConvergents::Stream Float" />
<div id="ansp12"><div></div></div>
```

</li>

</ul>

Compare this to the value of e computed by the

[exp](dbopexp.xhtml) operation in

[Float](db.xhtml?Float).

<ul>

<li>

```
<input type="submit" id="p13" class="subbut" onclick="makeRequest('p13');"
 value="exp 1.0" />
<div id="ansp13"><div></div></div>
```

</li>

</ul>

In about 1658, Lord Brouncker established the following expansion for 4/pi.

<pre>

```
1 + 1

2 + 9

2 + 25

2 + 49

2 + 81

2 + ...
```

</pre>

Let's use this expansion to compute rational and floating point approximations for pi.

<ul>

```

 <input type="submit" id="p14" class="subbut" onclick="makeRequest('p14');"
 value="cf:=continuedFraction(1,[(2*i+1)^2 for i in 0..],repeating [2])" />
 <div id="ansp14"><div></div></div>

 <input type="submit" id="p15" class="subbut"
 onclick="handleFree(['p14','p15']);"
 value="ccf:=convergents cf" />
 <div id="ansp15"><div></div></div>

 <input type="submit" id="p16" class="subbut"
 onclick="handleFree(['p14','p15','p16']);"
 value="piConvergents:=[4/p for p in ccf]" />
 <div id="ansp16"><div></div></div>

```

As you can see, the values are converging to

```

<pre>
 pi = 3.14159265358979323846..., but not very quickly.
</pre>

```

```

 <input type="submit" id="p17" class="subbut"
 onclick="handleFree(['p14','p15','p16','p17']);"
 value="piConvergents::Stream Float" />
 <div id="ansp17"><div></div></div>

```

You need not restrict yourself to continued fractions of integers. Here is an expansion for a quotient of Gaussian integers.

```

 <input type="submit" id="p18" class="subbut" onclick="makeRequest('p18');"
 value="continuedFraction((-122+597*i)/(4-4*i))" />
 <div id="ansp18"><div></div></div>

```

This is an expansion for a quotient of polynomials in one variable with rational number coefficients.

```

 <input type="submit" id="p19" class="subbut" onclick="makeRequest('p19');"
 value="r:Fraction UnivariatePolynomial(x,Fraction Integer)" />
 <div id="ansp19"><div></div></div>

```

```

 <input type="submit" id="p20" class="subbut"
 onclick="handleFree(['p19','p20']);"
 value="r:=((x-1)*(x-2))/((x-3)*(x-4))" />
 <div id="ansp20"><div></div></div>

 <input type="submit" id="p21" class="subbut"
 onclick="handleFree(['p19','p20','p21']);"
 value="continuedFraction r" />
 <div id="ansp21"><div></div></div>

```

To conclude this section, we give you evidence that

```

<pre>
z = 3 +

 3 +

 6 +

 3 +

 6 +

 3 + ...

```

```

</pre>

```

is the expansion of the square root of 11.

```

 <input type="submit" id="p22" class="subbut"
 onclick="handleFree(['p7','p22']);"
 value="[i*i for i in convergents(z)]:Stream Float" />
 <div id="ansp22"><div></div></div>

<page foot>

```

## 1.9.482 numexamples.xhtml

```

<numexamples.xhtml>≡
 <standard head>
 <script type="text/javascript">
 <handlefreevars>
 <axiom talker>
 </script>
 </head>
 <body>
 <page head>
 <div align="center">Examples</div>
 <hr/>

```

One can show that if an integer of the form  $2^{k+1}$  is prime, then  $k$  must be a power of two.

Pierre Fermat conjectured that every integer of the form  $2^{2^n} + 1$  is prime. Let's look for a counterexample. First define a function:

```

 <input type="submit" id="p1" class="noresult"
 onclick="makeRequest('p1');"
 value="f(n:NNI):INT == 2^(2^n)+1" />
 <div id="ansp1"><div></div></div>

```

Now try commands like:

```

 <input type="submit" id="p2" class="subbut"
 onclick="handleFree(['p1','p2']);"
 value="factor f(1)" />
 <div id="ansp2"><div></div></div>

 <input type="submit" id="p3" class="subbut"
 onclick="handleFree(['p1','p3']);"
 value="factor f(2)" />
 <div id="ansp3"><div></div></div>

```

until you find an integer of this form which is composite. You can also try the following command:

```

 <input type="submit" id="p4" class="subbut"

```

```
 onclick="handleFree(['p1','p4']);"
 value="[factor f(n) for n in 1..6]" />
 <div id="ansp4"><div></div></div>

Obviously, Fermat didn't have access to Axiom.
<page foot>
```

## 1.9.484 numfinitefields.xhtml

*(numfinitefields.xhtml)*≡

*(standard head)*

</head>

<body>

*(page head)*

<div align="center">Finite Fields</div>

<hr/>

A `<sl>finite field</sl>` (also called a `<sl>Galois field</sl>`) is a finite algebraic structure where one can add, multiply, and divide under the same laws (for example, commutativity, associativity, or distributivity) as apply to the rational, real, or complex numbers. Unlike those three fields, for any finite field there exists a positive prime integer  $p$ , called the `<a href="dbcharacteristic.xhtml">characteristic</a>`, such that  $p \cdot x = 0$  for any element  $x$  in the finite field. In fact, the number of elements in a finite field is a power of the characteristic and for each prime  $p$  and positive integer  $n$  there exists exactly one finite field with  $p^n$  elements, up to an isomorphism. (For more information about the algebraic structure and properties of finite fields, see for example, S. Lang `<sl>Algebr</sl>`, Second Edition, New York, Addison-Wesley Publishing Company, Inc. 1984, ISBN 0 201 05476 6; or R. Lidl, H. Niederreiter, `<sl>Finite Fields</sl>`, Encyclopedia of Mathematics and Its Applications, Vol. 20, Cambridge. Cambridge Univ. Press, 1983, ISBN 0 521 30240 4)

When  $n=1$ , the field has  $p$  elements and is called a `<sl>prime field</sl>`, discussed in

`<a href="axbook/section-8.11.xhtml#subsec-8.11.1">`

Modular Arithmetic and Prime Fields`</a>`

in section 8.11.1. There are several ways of implementing extensions of finite fields, and Axiom provides quite a bit of freedom to allow you to choose the one that is best for your application. Moreover, we provide operations for converting among the different representations of extensions and different extensions of a single field. Finally, note that you usually need to package call operations from finite fields if the operations do not take as an argument an object of the field. See

`<a href="">Package Calling and Target Types</a>`

in section 2.9 for more information on package calling.

```

<numfloat.xhtml>≡
 <standard head>
 </head>
 <body>
 <page head>
 <div align="center">Real Numbers</div>
 <hr/>
 Axiom provides two kinds of floating point numbers. The domain
 Float
 (abbreviation FLOAT)
 implements a model of arbitrary precisions floating point numbers. The
 domain
 DoubleFloat
 (abbreviation DFLOAT)
 is intended to make available hardware floating point arithmetic in Axiom.
 The actual model of floating point
 DoubleFloat that Axiom
 provides is system dependent. For example, on the IBM System 370, Axiom
 uses IBM double precision which has fourteen hexadecimal digits of
 precision or roughly sixteen decimal digits. Arbitrary precision floats
 allow the user to specify the precision at which arithmetic operations
 are computed. Although this is an attractive facility, it comes at a cost.
 Arbitrary precision floating point arithmetic typically takes twenty to
 two hundred times more time than hardware floating point.

```

For more information about Axiom's numeric and graphic facilities see <a href="axbook/book-contents.xhtml#chapter7">Graphics</a> in section 7, <a href="axbook/book-contents.xhtml#chapter8">Numeric Functions</a> in section 8.1, and <a href="nummachinefloats.xhtml">DoubleFloat</a>

## 1.9.487 numfunctions.xhtml

```

<numfunctions.xhtml>≡
 <standard head>
 <script type="text/javascript">
 <handlefreevars>
 <axiom talker>
 </script>
 </head>
 <body>
 <page head>
 <div align="center">Integer Number Theory Functions</div>
 <hr/>
 The
 IntegerNumberTheoryFunctions package contains a variety of
 operations of interest to number theorists. Many of these operations
 deal with divisibility properties of integers (Recall that an integer
 a divides an integer b if there is an integer c such that $b=a*c$.)

```

The operation <a href="dbopdivisors.xhtml">divisors</a> returns a list of the divisors of an integer

```

 <input type="submit" id="p1" class="subbut"
 onclick="makeRequest('p1');"
 value="div144:=divisors(144)" />
 <div id="ansp1"><div></div></div>

```

You can now compute the number of divisors of 144 and the sum of the divisors of 144 by counting and summing the elements of the list we just created.

```

 <input type="submit" id="p2" class="subbut"
 onclick="handleFree(['p1','p2']);"
 value="#(div144)" />
 <div id="ansp2"><div></div></div>

 <input type="submit" id="p3" class="subbut"
 onclick="handleFree(['p1','p3']);"
 value="reduce(+,div144)" />
 <div id="ansp3"><div></div></div>

```

Of course, you can compute the number of divisors of an integer  $n$ , usually denoted  $d(n)$ , and the sum of the divisors of an integer  $n$ , usually denoted  $\sigma(n)$ , without ever listing the divisors of  $n$ .

In Axiom, you can simply call the operations

```

 <input type="submit" id="p4" class="subbut"
 onclick="makeRequest('p4');"
 value="numberOfDivisors(144)" />
 <div id="ansp4"><div></div></div>

 <input type="submit" id="p5" class="subbut"
 onclick="makeRequest('p5');"
 value="sumOfDivisors(144)" />
 <div id="ansp5"><div></div></div>

```

The key is that  $d(n)$  and  $\sigma(n)$  are "multiplicative functions". This means that when  $n$  and  $m$  are relatively prime, that is, when  $n$  and  $m$  have no factors in common, then  $d(nm) = d(n)d(m)$  and  $\sigma(nm) = \sigma(n)\sigma(m)$ . Note that these functions are trivial to compute when  $n$  is a prime power and are computed for general  $n$  from the prime factorization of  $n$ . Other examples of multiplicative functions are  $\sigma_k(n)$ , the sum of the  $k$ -th powers of the divisors of  $n$  and  $\phi(n)$ , the number of integers between 1 and  $n$  which are prime to  $n$ . The corresponding Axiom operations are called [sumOfKthPowerDivisors](#) and [eulerPhi](#).

```

 <input type="submit" id="p6" class="subbut"
 onclick="makeRequest('p6');"
 value="sumOfKthPowerDivisors(144,2)" />
 <div id="ansp6"><div></div></div>

 <input type="submit" id="p7" class="subbut"
 onclick="makeRequest('p7');"
 value="eulerPhi(144)" />
 <div id="ansp7"><div></div></div>

```

An interesting function is called  $\mu(n)$ , the Moebius  $\mu$  function,

defined as

```
<pre>
 0 if n has a repeated prime factor
 (i.e. is divisible by a square)
 <(n)= 1 if n is 1
 (-1)^k if n is the product of k distinct primes
</pre>
```

The corresponding Axiom operation is

```

 <input type="submit" id="p8" class="subbut"
 onclick="makeRequest('p8');"
 value="moebiusMu(2*2*2)" />
 <div id="ansp8"><div></div></div>

 <input type="submit" id="p9" class="subbut"
 onclick="makeRequest('p9');"
 value="moebiusMu(1)" />
 <div id="ansp9"><div></div></div>

 <input type="submit" id="p10" class="subbut"
 onclick="makeRequest('p10');"
 value="moebiusMu(5*7*13)" />
 <div id="ansp10"><div></div></div>

```

This function occurs in the following theorem:

<br/>

<b>Theorem</b>(Moebius Inversion Formula):<br/>

Let  $f(n)$  be a function on the positive integers and let  $F(n)$  be defined by  $F(n) = \sum_{d|n} f(d)$  where the sum is taken over the positive divisors of  $n$ . Then the values of  $f(n)$  can be recovered from the values of  $F(n)$ :  $f(n) = \sum_{d|n} \mu(d) F(n/d)$  where the sum is taken over the positive divisors of  $n$ .

When  $f(n)=1$ , the  $F(n)=d(n)$ . Thus, if you sum  $\mu(d)*d(n/d)$  over the positive divisors of  $d$  of  $n$ , you should always get 1.

```

 <input type="submit" id="p11" class="noresult"
 onclick="makeRequest('p11');"
 value="f1(n)==reduce(+,[moebiusMu(d)*numberOfDivisors(quo(n,d)) for d in divisors
 <div id="ansp11"><div></div></div>

```

```

 <input type="submit" id="p12" class="subbut"
 onclick="handleFree(['p11','p12']);"
 value="f1(200)" />
 <div id="ansp12"><div></div></div>

 <input type="submit" id="p13" class="subbut"
 onclick="handleFree(['p11','p13']);"
 value="f1(846)" />
 <div id="ansp13"><div></div></div>

Similarly, when $f(n)=n$, then $F(n)=\sum_{d|n} \mu(d) \sum_{d|n} f(d)$. Thus, if you sum
 $\sum_{d|n} \mu(d) \sum_{d|n} f(d)$ over the positive divisors d of n , you
should always get n .

 <input type="submit" id="p14" class="noresult"
 onclick="makeRequest('p14');"
 value="f2(n)==reduce(+,[moebiusMu(d)*sumOfDivisors(quo(n,d)) for d in divisors(n)])" />
 <div id="ansp14"><div></div></div>

 <input type="submit" id="p15" class="subbut"
 onclick="handleFree(['p14','p15']);"
 value="f2(200)" />
 <div id="ansp15"><div></div></div>

 <input type="submit" id="p16" class="subbut"
 onclick="handleFree(['p14','p16']);"
 value="f2(846)" />
 <div id="ansp16"><div></div></div>

The Fibonacci numbers are defined by
<pre>
F(1)=1
F(2)=1
F(n)=F(n-1)+F(n-2) for n=3,4,...
</pre>
The operation fibonacci computes the
nth Fibonacci number.

```

```

<div></div></div>

<div></div></div>

```

Fibonacci numbers can also be expressed as sums of binomial coefficients.

```

<div></div></div>

<div></div></div>

<div></div></div>

```

Quadratic symbols can be computed with the operations

<dboplegendre.xhtml> and <dbopjacobi.xhtml>. The Legendre symbol  $(a/p)$  is defined for integers  $a$  and  $p$  with  $p$  an odd prime number. By definition,

```

<pre>
 = -1 when a is not a square (mod p)
 (a/p) = 0 when a is divisible by p
 = +1 when a is a square (mod p)
</pre>

```

You compute  $(a/p)$  via the command `legendre(a,p)`

```

```

```

 <input type="submit" id="p22" class="subbut"
 onclick="makeRequest('p22');"
 value="legendre(3,5)" />
 <div id="ansp22"><div></div></div>

 <input type="submit" id="p23" class="subbut"
 onclick="makeRequest('p23');"
 value="legendre(23,691)" />
 <div id="ansp23"><div></div></div>

```

The Jacobi symbol  $(a/n)$  is the usual extension of the Legendre symbol, where  $n$  is an arbitrary integer. The most important property of the Jacobi symbol is the following: if  $K$  is a quadratic field with discriminant  $d$  and quadratic character  $\chi$ , the  $\chi(n) = (d/n)$ . Thus, you can use the Jacobi symbol to compute, say, the class numbers of imaginary quadratic fields from a standard class number formula. This function computes the class number of the imaginary quadratic field with discriminant  $d$ .

```

 <input type="submit" id="p24" class="noresult"
 onclick="makeRequest('p24');"
 value="h(d)==quo(reduce(+,[jacobi(d,k) for k in 1..quo(-d,2)]),2-jacobi(d,2))" />
 <div id="ansp24"><div></div></div>

 <input type="submit" id="p25" class="subbut"
 onclick="handleFree(['p24','p25']);"
 value="h(-163)" />
 <div id="ansp25"><div></div></div>

 <input type="submit" id="p26" class="subbut"
 onclick="handleFree(['p24','p26']);"
 value="h(-499)" />
 <div id="ansp26"><div></div></div>

 <input type="submit" id="p27" class="subbut"
 onclick="handleFree(['p24','p27']);"
 value="h(-1832)" />
 <div id="ansp27"><div></div></div>

```

```

 <page foot>

```

### 1.9.488 numgeneralinfo.xhtml

```

<numgeneralinfo.xhtml>≡
 <standard head>
 </head>
 <body>
 <page head>
 <div align="center">General Integer Information</div>
 <hr/>
 Axiom provides many operations for manipulating arbitrary precision integers.
 In this section we will show some of those that come from
 Integer itself plus some that are implemented
 in other packages. More examples of integers are in the following sections:
 Numbers.
 IntegerNumberTheoryFunctions,
 DecimalExpansion,
 BinaryExpansion,
 HexadecimalExpansion, and
 RadixExpansion

 Basic Functions

 Some Number Theoretic Functions

```

## 1.9.490 numintegers.xhtml

```

<numintegers.xhtml>≡
 <standard head>
 <script type="text/javascript">
 <handlefreevars>
 <axiom talker>
 </script>
 </head>
 <body onload="resetvars();">
 <page head>
 <div align="center">Integers</div>
 <hr/>

```

In Axiom, integers can be as large as you like. Try the following examples.

```

 <input type="submit" id="p1" value="x:=factorial(200)" class="subbut"
 onclick="makeRequest('p1');"/>
 <div id="ansp1"><div></div></div>

 <input type="submit" id="p2" value="y:=2^90-1" class="subbut"
 onclick="makeRequest('p2');"/>
 <div id="ansp2"><div></div></div>

```

Of course, you can now do arithmetic as usual on these (very) large integers:

```

 <input type="submit" id="p3" value="x+y" class="subbut"
 onclick="handleFree(['p1','p2','p3']);"/>
 <div id="ansp3"><div></div></div>

 <input type="submit" id="p4" value="x-y" class="subbut"
 onclick="handleFree(['p1','p2','p4']);"/>
 <div id="ansp4"><div></div></div>

 <input type="submit" id="p5" value="x*y" class="subbut"
 onclick="handleFree(['p1','p2','p5']);"/>
 <div id="ansp5"><div></div></div>

```

Axiom can factor integers, but numbers with small prime factors

```

 <input type="submit" id="p6" value="factor(x)" class="subbut"
 onclick="handleFree(['p1','p6']);"/>
 <div id="ansp6"><div></div></div>

```

```

 will factor more rapidly than numbers with large prime factors.

 <input type="submit" id="p7" value="factor(y)" class="subbut"
 onclick="handleFree(['p2','p7']);"/>
 <div id="ansp7"><div></div></div>

### 1.9.491 nummachinefloats.xhtml

```

<nummachinefloats.xhtml>≡
 <standard head>
 <script type="text/javascript">
 <handlefreevars>
 <axiom talker>
 </script>
 </head>
 <body onload="resetvars();">
 <page head>
 <div align="center">Machine Floats</div>
 <hr/>
 Axiom provides two kinds of floating point numbers. The domain
 Float
 (abbreviation FLOAT)
 implements a model of arbitrary precisions floating point numbers. The
 domain
 DoubleFloat
 (abbreviation DFLOAT)
 is intended to make available hardware floating point arithmetic in Axiom.
 The actual model of floating point
 DoubleFloat that Axiom
 provides is system dependent. For example, on the IBM System 370, Axiom
 uses IBM double precision which has fourteen hexadecimal digits of
 precision or roughly sixteen decimal digits. Arbitrary precision floats
 allow the user to specify the precision at which arithmetic operations
 are computed. Although this is an attractive facility, it comes at a cost.
 Arbitrary precision floating point arithmetic typically takes twenty to
 two hundred times more time than hardware floating point.

 By default, floating point numbers that you enter into Axiom are of type
 Float.

 <input type="submit" id="p1" class="subbut"
 onclick="makeRequest('p1');"
 value="2.71828" />
 <div id="ansp1"><div></div></div>

 You must therefore tell Axiom that you want to use
 DoubleFloat values and operations. The
 following are some conservative guidelines for getting Axiom to use
 DoubleFloat.

```

To get a value of type `<a href="db.xhtml?DoubleFloat">DoubleFloat</a>.`, use a target with

"@", ...

```

 <input type="submit" id="p2" class="subbut"
 onclick="makeRequest('p2');"
 value="2.71828@DoubleFloat" />
 <div id="ansp2"><div></div></div>

```

a conversion,...

```

 <input type="submit" id="p3" class="subbut"
 onclick="makeRequest('p3');"
 value="2.71828::DoubleFloat" />
 <div id="ansp3"><div></div></div>

```

or an assignment to a declared variable. It is more efficient if you use a target rather than an explicit or implicit conversion.

```

 <input type="submit" id="p4" class="subbut"
 onclick="makeRequest('p4');"
 value="eApprox:DoubleFloat:=2.71828" />
 <div id="ansp4"><div></div></div>

```

You also need to declare functions that work with

`<a href="db.xhtml?DoubleFloat">DoubleFloat</a>.`

```

 <input type="submit" id="p5" class="noresult"
 onclick="makeRequest('p5');"
 value="avg:List DoubleFloat -> DoubleFloat" />
 <div id="ansp5"><div></div></div>

 <input type="submit" id="p6" class="noresult"
 onclick="makeRequest('p6');"
 value="avg l==(empty? l => 0::DoubleFloat; reduce(_+,l)/#l)"/>
 <div id="ansp6"><div></div></div>

```

```

<div></div></div>

<div></div></div>

```

Use package calling for operations from

```

DoubleFloat
unless the arguments themselves are already of type
DoubleFloat.

```

```

<div></div></div>

<div></div></div>

```

By far, the most common usage of

```

DoubleFloat
is for functions to be graphied. For more information about Axiom's
numerical and graphical facilities, see
Graphics
in section 7,
Numeric Functions
in section 8.1, and
Float

```

The usual arithmetic and elementary functions are available for

```

DoubleFloat. Use

```

```
value=")show DoubleFloat"/>
<div id="ansp11"><div></div></div>

to get a list of operations.
<page foot>
```

### 1.9.492 nummachinesizedintegers.xhtml

```

<nummachinesizedintegers.xhtml>≡
 <standard head>
 <script type="text/javascript">
 <handlefreevars>
 <axiom talker>
 </script>
 </head>
 <body onload="resetvars();">
 <page head>
 <div align="center">Machine-sized Integers</div>
 <hr/>
 The SingleInteger is intended to
 provide support in Axiom for machine integer arithmetic. It is generally
 much faster than (bignum) Integer arithmetic
 but suffers from a limited range of values. Since Axiom can be implemented
 on top of various dialects of Lisp, the actual representation of small
 integers may not correspond exactly to the host machines integer
 representation.

```

You can discover the minimum and maximum values in your implementation by using <a href="dbopmin.xhtml">min</a> and <a href="dbopmax.xhtml">max</a>

```

 <input type="submit" id="p1" class="subbut" onclick="makeRequest('p1');"
 value="min()$SingleInteger" />
 <div id="ansp1"><div></div></div>

 <input type="submit" id="p2" class="subbut" onclick="makeRequest('p2');"
 value="max()$SingleInteger" />
 <div id="ansp2"><div></div></div>

```

To avoid confusion with <a href="db.xhtml?Integer">Integer</a>, which is the default type for integers, you usually need to work with declared variables (see <a href="axbook/section-2.3.xhtml">Declarations</a>).

```

 <input type="submit" id="p3" class="subbut" onclick="makeRequest('p3');"
 value="a:=1234::SingleInteger" />
 <div id="ansp3"><div></div></div>

```

or use package calling (see

```

Package Calling and Target Types).

 <input type="submit" id="p4" class="subbut" onclick="makeRequest('p4');"
 value="b:=1234$SingleInteger" />
 <div id="ansp4"><div></div></div>

```

You can add, multiply, and subtract

[SingleInteger](db.xhtml?SingleInteger) objects, and ask for the greatest common divisor

([gcd](dbopgcd.xhtml)).

```

 <input type="submit" id="p5" class="subbut"
 onclick="handleFree(['p3','p4','p5']);"
 value="gcd(a,b)" />
 <div id="ansp5"><div></div></div>

```

The least common multiple

([lcm](dboplcm.xhtml)) is also available.

```

 <input type="submit" id="p6" class="subbut"
 onclick="handleFree(['p3','p4','p6']);"
 value="lcm(a,b)" />
 <div id="ansp6"><div></div></div>

```

Operations

[mulmod](dbopmulmod.xhtml),

[addmod](dbopaddmod.xhtml),

[submod](dbopsubmod.xhtml), and

[invmod](dbopinvmmod.xhtml)

are similar -- they provide arithmetic modulo a given small integer.

Here is  $5 \cdot 6 \bmod 13$ .

```

 <input type="submit" id="p7" class="subbut" onclick="makeRequest('p7');"
 value="mulmod(5,6,13)$SingleInteger" />
 <div id="ansp7"><div></div></div>

```

To reduce a small integer modulo a prime, use

[positiveRemainder](dboppositiveremainder.xhtml)

```

 <input type="submit" id="p8" class="subbut" onclick="makeRequest('p8');"
 value="positiveRemainder(37,13)$SingleInteger" />
 <div id="ansp8"><div></div></div>

Operations And,
Or,
xor,
and Not
provide bit level operations on small integers.

 <input type="submit" id="p9" class="subbut" onclick="makeRequest('p9');"
 value="And(3,4)$SingleInteger" />
 <div id="ansp9"><div></div></div>

Use shift(int,numToShift) to shift bits, where int is shifted left if
numToShift is positive, right if negative.

 <input type="submit" id="p10" class="subbut" onclick="makeRequest('p10');"
 value="shift(1,4)$SingleInteger" />
 <div id="ansp10"><div></div></div>

 <input type="submit" id="p11" class="subbut" onclick="makeRequest('p11');"
 value="shift(31,-1)$SingleInteger" />
 <div id="ansp11"><div></div></div>

Many other operations are available for small integers, including many of
those provided for Integer.
To see other operations use the system command

 <input type="submit" id="p12" class="subbut"
 onclick="showcall('p12');"
 value=")show SingleInteger"/>
 <div id="ansp12"><div></div></div>

### 1.9.494 numnumericfunctions.xhtml

```

<numnumericfunctions.xhtml>≡
 <standard head>
 <script type="text/javascript">
 <handlefreevars>
 <axiom talker>
 </script>
 </head>
 <body onload="resetvars();">
 <page head>
 <div align="center">Numeric Functions</div>
 <hr/>
 Axiom provides two basic floating point types:
 Float and
 DoubleFloat. This section
 describes how to use numerical operations defined on these types and
 the related complex types. As we mentioned in
 An Overview of Axiom
 in chapter 1., the
 Float type is a software implementation of
 floating point numbers in which the exponent and the significand may have
 any number of digits. See
 Float for detailed information about this
 domain. The
 DoubleFloat is usually a hardware
 implementation of floating point numbers, corresponding to machine double
 precision. The types
 Complex Float and
 Complex DoubleFloat are the
 corresponding software implementations of complex floating point numbers.
 In this section the term floating point type means any of these four
 types. The floating point types implement the basic elementary functions.
 These include (where $ means
 DoubleFloat,
 Float,
 Complex Float,
 Complex DoubleFloat):

 exp,
 log: $ -> $

 sin,
 cos,
 tan,
 cot,
 sec,
 csc: $ -> $

```

```

asin,
acos,
atan,
acot,
asec,
acsc: $ -> $

sinh,
cosh,
tanh,
coth,
sech,
csch: $ -> $

asinh,
acosh,
atanh,
acoth,
asech,
acsch: $ -> $

pi: () -> $

sqrt: $ -> $

nthRoot: ($,Integer) -> $

*: ($,Fraction Integer) -> $

*: ($,$) -> $

```

The handling of roots depends on whether the floating point type is real or complex: for the real floating point types,

[DoubleFloat](nummachinefloats.xhtml) and

[Float](numfloat.xhtml), if a real root exists the one with the same sign as the radicand is returned; for the complex floating point types, the principal value is returned. Also, for real floating point types the inverse functions produce errors if the results are not real. This includes cases such as `asin(1.2)`, `log(-3.2)`, `sqrt(-1,1)`. The default floating point type is [Float](numfloat.xhtml) or [Complex Float](dbcomplexfloat.xhtml), just use normal decimal notation.

```

```

```

```

```

 <input type="submit" id="p1" class="subbut" onclick="makeRequest('p1');"
 value="exp(3.1)" />

```

```
 <div id="ansp1"><div></div></div>
```

```

```

```

```

```

 <input type="submit" id="p2" class="subbut" onclick="makeRequest('p2');"
 value="exp(3.1+4.5*i)" />

```

```
 <div id="ansp2"><div></div></div>
```

```

```

```

```

To evaluate functions using

[DoubleFloat](nummachinefloats.xhtml) or  
[Complex DoubleFloat](dbcomplexdoublefloat.xhtml), a  
 declaration or conversion is required.

```

 <input type="submit" id="p3" class="subbut" onclick="makeRequest('p3');"
 value="(r:DFLOAT:=3.1; t:DFLOAT:=4.5; exp(r+t*%i))" />
 <div id="ansp3"><div></div></div>

 <input type="submit" id="p4" class="subbut" onclick="makeRequest('p4');"
 value="exp(3.1::DFLOAT+4.5::DFLOAT*%i)" />
 <div id="ansp4"><div></div></div>

```

A number of special functions are provided by the package

[DoubleFloatSpecialFunctions](db.xhtml?DoubleFloatSpecialFunctions)

for the machine precision floating point types. The special functions  
 provided are listed below, where F stands for the types

[Float](numfloat.xhtml)

or [Complex Float](dbcomplexfloat.xhtml). The real versions  
 of the functions yield an error if the result is not real.

```

 Gamma: F -> F

 Gamma(z) is the Euler gamma
 function, Gamma(Z), defined by

 Gamma(z) = integrate(t^(z-1)*exp(-t),t=0..%infinity)

 Beta: F -> F

 Beta(u,v) is the Euler Beta
 function B(u,v), defined by

 Beta(u,v)=integrate(t^(u-1)*(1-t)^(b-1),t=0..1)

 This is related to Gamma(z) by

 Beta(u,v)=Gamma(u)*Gamma(v)/Gamma(u+v)

 logGamma: F -> F

 logGamma(z) is the natural logarithm of Gamma(z). This can often be
 computed even if Gamma(z) cannot.

 digamma: F -> F

 digamma(z), also called psi(z), is the function psi(z), defined by

```

```

 psi(z)=Gamma'(z)/Gamma(z)

 polygamma: (NonNegativeInteger, F) -> F

 polygamma(n,z) is the n-th derivative of digamma(z)

 besselJ: (F, F) -> F

 besselJ(v,z) is the Bessel function of the first kind, J(v,z). This
 function satisfies the differential equation

$$z^2 w''(z) + zw'(z) + (z^2 - v^2)w(z) = 0$$

 besselY: (F, F) -> F

 besselY(v,z) is the Bessel function of the second kind, Y(v,z). This
 function satisfies the same differential equation as
 besselJ. The implementation simply
 uses the relation

$$Y(v,z) = (J(v,z)\cos(v\pi) - J(-v,z))/\sin(v\pi)$$

 besselI: (F, F) -> F

 besselI(v,z) is the modified Bessel function of the first kind, I(v,z).
 This function satisfies the differential equation

$$z^2 w''(z) + zw'(z) - (z^2 + v^2)w(z) = 0$$

 besselK: (F, F) -> F

 besselK(v,z) is the modified Bessel function of the second kind, K(v,z).
 This function satisfies the same differential equation as
 besselI. The implementation simply uses
 the relation

$$K(v,z) = \pi(I(v,z) - I(-v,z))/(2\sin(v\pi))$$

 airyAi: F -> F

 airyAi(z) is the Airy function Ai(z). This function satisfies the
 differential equation

$$w''(z) - zw(z) = 0$$

 The implementation simply uses the relation

$$Ai(-z) = 1/3\sqrt{z}(J(-1/3, 2/3z^{3/2}) + J(1/3, 2/3z^{3/2}))$$

 airyBi: F -> F

 airyBi(z) is the Airy function Bi(z). This function satisfies the
 same differential equation as airyAi.

```

The implementation simply uses the relation  

$$\text{Bi}(-z) = \frac{1}{3} \sqrt{3z} (J(-\frac{1}{3}, \frac{2}{3}z^{(3/2)}) - J(\frac{1}{3}, \frac{2}{3}z^{(3/2)}))$$

[hypergeometric0F1](dbophypergeometric0f1.xhtml):  $(F, F) \rightarrow F$   
[hypergeometric0F1\(c,z\)](dbophypergeometric0f1.xhtml) is the hypergeometric function  ${}_0F_1(;c;z)$ . The above special functions are defined only for small floating point types. If you give [Float](numfloat.xhtml) arguments, they are converted to [DoubleFloat](nummachinefloats.xhtml) by Axiom.

<br>  

</div></div>

<br>  

</div></div></div>

A number of additional operations may be used to compute numerical values. These are special polynomial functions that can be evaluated for values in any commutative ring  $R$ , and in particular for values in any floating-point type. The following operations are provided by the package [OrthogonalPolynomialFunctions](db.xhtml?OrthogonalPolynomialFunctions):

[chebyshevT](dbopchebyshevt.xhtml):  
 $(\text{nonNegativeInteger}, R) \rightarrow R$   
  
 $\text{chebyshevT}(n, z)$  is the  $n$ th Chebyshev polynomial of the first kind,  $T[n](z)$ . These are defined by  
  

$$(1-tz)/(1-2tz+t^2) = \sum (T[n](z) \cdot t^n, n=0..)$$

[chebyshevU](dbopchebyshevu.xhtml):  
 $(\text{nonNegativeInteger}, R) \rightarrow R$   
  
 $\text{chebyshevU}(n, z)$  is the  $n$ th Chebyshev polynomial of the second kind,  $U[n](z)$ . These are defined by  
  

$$1/(1-2tz+t^2) = \sum (U[n](z) \cdot t^n, n=0..)$$

[hermiteH](dbophermiteh.xhtml):  
 $(\text{NonNegativeInteger}, R) \rightarrow R$

```

 hermiteH(n,z) is the nth Hermite polynomial, $H[n](z)$. These are
 defined by

 exp(2*t*z-t**2)=sum(H[n](z)*t**n/n!,n=0..)

 laguerreL:
 (NonNegativeInteger,R) -> R

 laguerreL(n,z) is the nth Laguerre polynomial, $L[n](z)$. These are
 defined by

 (exp(-t*z/(1-t))/(1-t)=sum(L[n](z)*t**n/n!,n=0..)

 laguerreL:
 (NonNegativeInteger,NonNegativeInteger,R) -> R

 labuerreL(m,n,2) is the associated Laguerre polynomial, $L\< m>[n](z)$.
 This is the nth derivative of $L[n](z)$.

 legendreP:
 (NonNegativeInteger,R) -> R

 legendreP(n,z) is the nth Legendre polynomial, $P[n](z)$. These are
 defined by

 1/sqrt(1-2*z*t+t**2)=sum(P[n](z)*t**n,n=0..)

These operations require non-negative integers for the indices,
but otherwise the argument can be given as desired.

 <input type="submit" id="p7" class="subbut"
 onclick="makeRequest('p7');"
 value="[chebyshevT(i,z) for i in 0..5]" />
 <div id="ansp7"><div></div></div>

The expression chebyshevT(n,z) evaluates to the nth Chebyshev polynomial
of the first kind.

 <input type="submit" id="p8" class="subbut"

```

```

 onclick="makeRequest('p8');"
 value="chebyshevT(3,5.0+6.0*%i)" />
 <div id="ansp8"><div></div></div>

 value="[laguerreL(j,3,z) for j in 0..4]" />
 <div id="ansp16"><div></div></div>

 <input type="submit" id="p17" class="subbut"
 onclick="makeRequest('p17');"
 value="laguerreL(1,3,2.1)" />
 <div id="ansp17"><div></div></div>

```

The expression `legendreP(n,z)` evaluates to the  $n$ th Legendre polynomial.

```

 <input type="submit" id="p18" class="subbut"
 onclick="makeRequest('p18');"
 value="[legendreP(i,z) for i in 0..5]" />
 <div id="ansp18"><div></div></div>

 <input type="submit" id="p19" class="subbut"
 onclick="makeRequest('p19');"
 value="legendreP(3,3.0*i)" />
 <div id="ansp19"><div></div></div>

```

Finally, three number-theoretic polynomial operations may be evaluated.

The following operations are provided by the package

```

```

```
NumberTheoreticPolynomialFunctions.
```

```

```

```
 bernoulliB:
```

```

 (NonNegativeInteger,R) -> R

 bernoulliB(n,z) is the nth Bernoulli polynomial, B[n](z). These are
 defined by

 t*exp(z*t)/(exp t - 1)=sum(B[n](z)*t**n/n! for n=0..)

 eulerE:
 (NonNegativeInteger,R) -> R

 eulerE(n,z) is the nth Euler polynomial, E[n](z). These are defined by

 2*exp(z*t)/(exp t + 1)=sum(E[n](z)*t**n/n! for n=0..)

 cyclotomic:
 (NonNegativeInteger,R) -> R

 cyclotomic(n,z) is the nth cyclotomic polynomial $\phi_n(z)$.
 This is the polynomial whose roots are precisely the primitive nth
 roots of unity. This polynomial has degree given by the Euler
 totient function $\phi(n)$.

```

The expression bernoulliB(n,z) evaluates to the nth Bernoulli polynomial.

```

 <input type="submit" id="p20" class="subbut"
 onclick="makeRequest('p20');"
 value="bernoulliB(3,z)" />
 <div id="ansp20"><div></div></div>

 <input type="submit" id="p21" class="subbut"
 onclick="makeRequest('p21');"
 value="bernoulliB(3,0.7+0.4*i)" />
 <div id="ansp21"><div></div></div>

```

The expression eulerE(n,z) evaluates to the nth Euler polynomial.

```

 <input type="submit" id="p22" class="subbut"
 onclick="makeRequest('p22');"
 value="eulerE(3,z)" />
 <div id="ansp22"><div></div></div>

```

```

 <input type="submit" id="p23" class="subbut"
 onclick="makeRequest('p23');"
 value="eulerE(3,0.7+0.4*i)" />
 <div id="ansp23"><div></div></div>

```

The expression `cyclotomic(n,z)` evaluates to the  $n$ th cyclotomic polynomial.

```

 <input type="submit" id="p24" class="subbut"
 onclick="makeRequest('p24');"
 value="cyclotomic(3,z)" />
 <div id="ansp24"><div></div></div>

 <input type="submit" id="p25" class="subbut"
 onclick="makeRequest('p25');"
 value="cyclotomic(3,(-1.0+0.0*i)**(2/3))" />
 <div id="ansp25"><div></div></div>

```

Drawing complex functions in Axiom is presently somewhat awkward compared to drawing real functions. It is necessary to use the [draw](dbopdraw.xhtml) operations that operate on functions rather than expressions.

This is the complex exponential function. When this is displayed in color, the height is the value of the real part of the function and the color is the imaginary part. Red indicates large negative imaginary values, green indicates imaginary values near zero and blue/violet indicates large positive imaginary values.

```

 <input type="submit" id="p26" class="subbut"
 onclick="makeRequest('p26');"
 value='draw((x,y)-->real exp complex(x,y),-2..2,-2*pi..2*pi,colorFunction==(x,y)-->imag e
 <div id="ansp26"><div></div></div>

```

This is the complex arctangent function. Again, the height is the real part of the function value but here the color indicates the function value's phase. The position of the branch cuts are clearly visible and one can see that the

function is real only for a real argument.

```

 <input type="submit" id="p27" class="subbut"
 onclick="makeRequest('p27');"
 value='vp:=draw((x,y)+->real atan complex(x,y),-%pi..%pi,-%pi..%pi,colorFunction
 <div id="ansp27"><div></div></div>

```

This is the complex Gamma function.

```

 <input type="submit" id="p28" class="subbut"
 onclick="makeRequest('p28');"
 value='draw((x,y)+->max(min(real Gamma complex(x,y),4),-4),-%pi..%pi,-%pi..%pi,st
 <div id="ansp28"><div></div></div>

```

This shows the real Beta function near the origin.

```

 <input type="submit" id="p29" class="subbut"
 onclick="makeRequest('p29');"
 value='draw(Beta(x,y)/100,x=-1.6..1.7,y=-1.6..1.7,style=="shade",title=="Beta(x,y
 <div id="ansp29"><div></div></div>

```

This is the Bessel function  $J(\alpha, x)$  for index  $\alpha$  in the range  $-6..4$  and argument  $x$  in the range  $2..14$ .

```

 <input type="submit" id="p30" class="subbut"
 onclick="makeRequest('p30');"
 value='draw((alpha,x)+->min(max(besselJ(alpha,x+8),-6), 6),-6..4,-6..6,title=="b
 <div id="ansp30"><div></div></div>

```

This is the modified Bessel function  $I(\alpha, x)$  evaluated for various real values of the index  $\alpha$  and fixed argument  $x=5$ .

```

 <input type="submit" id="p31" class="subbut"
 onclick="makeRequest('p31');"
 value="draw(besselI(alpha,5),alpha=-12..12,unit==[5,20])" />
 <div id="ansp31"><div></div></div>

```

</ul>

This is similar to the last example except the index  $\alpha$  takes on complex values in a 6x6 rectangle centered on the origin.

<ul>

<li>

<input type="submit" id="p32" class="subbut"

onclick="makeRequest('p32');"

value='draw((x,y)+->real besseli(complex(x/20,y/20),5),-60..60,-60..60,colorFunction==(x,y)

<div id="ansp32"><div></div></div>

</li>

</ul>

<page foot>

## 1.9.495 numoctonions.xhtml

```

<numoctonions.xhtml>≡
 <standard head>
 <script type="text/javascript">
 <handlefreevars>
 <axiom talker>
 </script>
 </head>
 <body onload="resetvars();">
 <page head>
 <div align="center">Octonions</div>
 <hr/>

```

The Octonions, also called the Cayley-Dixon algebra, defined over a commutative ring are an eight-dimensional non-associative algebra. Their construction from quaternions is similar to the construction of quaternions from complex numbers (see [Quaternion](numquaternions.xhtml)). As [Octonion](db.xhtml?Octonion) creates an eight-dimensional algebra, you have to give eight components to construct an octonion.

```

 <input type="submit" id="p1" class="subbut" onclick="makeRequest('p1');"
 value="oci1:=octon(1,2,3,4,5,6,7,8)" />
 <div id="ansp1"><div></div></div>

 <input type="submit" id="p2" class="subbut" onclick="makeRequest('p2');"
 value="oci2:=octon(7,2,3,-4,5,6,-7,0)" />
 <div id="ansp2"><div></div></div>

```

Or you can use two quaternions to create an octonion.

```

 <input type="submit" id="p3" class="subbut" onclick="makeRequest('p3');"
 value="oci3:=octon(quatern(-7,-12,3,-10),quatern(5,6,9,0))" />
 <div id="ansp3"><div></div></div>

```

You can easily demonstrate the non-associativity of multiplication.

```

 <input type="submit" id="p4" class="subbut"
 onclick="handleFree(['p1','p2','p3','p4']);"
 value="(oci1*oci2)*oci3-oci1*(oci2*oci3)" />
 <div id="ansp4"><div></div></div>

```

```

```

As with the quaternions, we have a real part, the imaginary parts  $i, j, k$ , and four additional imaginary parts  $E, I, J$ , and  $K$ . These parts correspond to the canonical basis  $(1, i, j, k, E, I, J, K)$ . For each basis element there is a component operation to extract the coefficient of the basis element for a given octonion.

```

 <input type="submit" id="p5" class="subbut"
 onclick="handleFree(['p1','p5']);"
 value="[real oci1, imagi oci1, imagj oci1, imagk oci1,
 imagE oci1, imagI oci1, imagJ oci1, imagK oci1]"/>
 <div id="ansp5"><div></div></div>

```

A basis with respect to the quaternions is given by  $(1, E)$ . However, you might ask, what then are the commuting rules? To answer this, we create some generic elements. We do this in Axim by simply changing the ground ring from

```

Integer to
Polynomial Integer.

 <input type="submit" id="p6" class="subbut" onclick="makeRequest('p6');"
 value="q:Quaternion Polynomial Integer:=quatern(q1,qi,qj,qk)" />
 <div id="ansp6"><div></div></div>

 <input type="submit" id="p7" class="subbut" onclick="makeRequest('p7');"
 value="E:Octonion Polynomial Integer:=octon(0,0,0,0,1,0,0,0)" />
 <div id="ansp7"><div></div></div>

```

Note that quaternions are automatically converted to octonions in the obvious way.

```

 <input type="submit" id="p8" class="subbut"
 onclick="handleFree(['p6','p7','p8']);"
 value="q*E" />
 <div id="ansp8"><div></div></div>

 <input type="submit" id="p9" class="subbut"
 onclick="handleFree(['p6','p7','p9']);"

```

```

 value="E*q" />
 <div id="ansp9"><div></div></div>

 <input type="submit" id="p10" class="subbut"
 onclick="handleFree(['p6','p10']);"
 value="q*1$(Octonion Polynomial Integer)" />
 <div id="ansp10"><div></div></div>

 <input type="submit" id="p11" class="subbut"
 onclick="handleFree(['p6','p11']);"
 value="1$(Octonion Polynomial Integer)*q" />
 <div id="ansp11"><div></div></div>

```

Finally, we check that the [norm](dbopnorm.xhtml), defined as the sum of the squares of the coefficients, is a multiplicative map.

```

 <input type="submit" id="p12" class="subbut" onclick="makeRequest('p12');"
 value="o:Octonion Polynomial Integer:=octon(o1,oi,oj,ok,oE,oI,oJ,oK)" />
 <div id="ansp12"><div></div></div>

 <input type="submit" id="p13" class="subbut"
 onclick="handleFree(['p12','p13']);"
 value="norm o" />
 <div id="ansp13"><div></div></div>

 <input type="submit" id="p14" class="subbut" onclick="makeRequest('p14');"
 value="p:Octonion Polynomial Integer:=octon(p1,pi,pj,pk,pE,pI,pJ,pK)" />
 <div id="ansp14"><div></div></div>

```

Since the result is 0, the norm is multiplicative

```

 <input type="submit" id="p15" class="subbut"
 onclick="handleFree(['p12','p14','p15']);"
 value="norm(o*p)-norm(o)*norm(p)" />
 <div id="ansp15"><div></div></div>

```

Issue the system command

```

 <input type="submit" id="p16" class="subbut"
 onclick="showcall('p16');"
 value=")show Octonion"/>
 <div id="ansp16"><div></div></div>

to display the list of operations defined by
Octonion.
<page foot>
```

## 1.9.496 numotherbases.xhtml

```

<numotherbases.xhtml>≡
 <standard head>
 <script type="text/javascript">
 <handlefreevars>
 <axiom talker>
 </script>
 </head>
 <body onload="resetvars();">
 <page head>
 <div align="center">Expansions in other Bases</div>
 <hr/>
 It is possible to expand numbers in general bases. Here we expand
 111 in base 5. This means
 <pre>
 2 1 0 2 1 -
 10 +10 +10 = 4*5 +2*5 +5
 </pre>

 <input type="submit" id="p1" class="subbut" onclick="makeRequest('p1');"
 value="111::RadixExpansion(5)" />
 <div id="ansp1"><div></div></div>

 You can expand fractions to form repeating expansions.

 <input type="submit" id="p2" class="subbut" onclick="makeRequest('p2');"
 value="(5/24)::RadixExpansion(2)" />
 <div id="ansp2"><div></div></div>

 <input type="submit" id="p3" class="subbut" onclick="makeRequest('p3');"
 value="(5/24)::RadixExpansion(3)" />
 <div id="ansp3"><div></div></div>

 <input type="submit" id="p4" class="subbut" onclick="makeRequest('p4');"
 value="(5/24)::RadixExpansion(8)" />
 <div id="ansp4"><div></div></div>

 <input type="submit" id="p5" class="subbut" onclick="makeRequest('p5');"
 value="(5/24)::RadixExpansion(10)" />

```

```

 <div id="ansp5"><div></div></div>

For bases from 11 to 36 the letters A through Z are used.

 <input type="submit" id="p6" class="subbut" onclick="makeRequest('p6');"
 value="(5/24)::RadixExpansion(12)" />
 <div id="ansp6"><div></div></div>

 <input type="submit" id="p7" class="subbut" onclick="makeRequest('p7');"
 value="(5/24)::RadixExpansion(16)" />
 <div id="ansp7"><div></div></div>

 <input type="submit" id="p8" class="subbut" onclick="makeRequest('p8');"
 value="(5/24)::RadixExpansion(36)" />
 <div id="ansp8"><div></div></div>

For bases greater than 36, the ragits are separated by blanks.

 <input type="submit" id="p9" class="subbut" onclick="makeRequest('p9');"
 value="(5/24)::RadixExpansion(38)" />
 <div id="ansp9"><div></div></div>

The RadixExpansion type provides
operations to obtain the individual ragits. Here is a rational number
in base 8.

 <input type="submit" id="p10" class="subbut" onclick="makeRequest('p10');"
 value="a:=(76543/210)::RadixExpansion(8)" />
 <div id="ansp10"><div></div></div>

The operation wholeRagits returns
a list of the ragits for the integral part of the number.

 <input type="submit" id="p11" class="subbut"
 onclick="handleFree(['p10','p11']);"
 value="w:=wholeRagits a" />

```

```

 <div id="ansp11"><div></div></div>

```

The operations [prefixRagits](dbopprefixragits.xhtml) and [cycleRagits](dbopcycleraigits.xhtml) returns lists of the initial and repeating ragits in the fractional part of the number.

```

 <input type="submit" id="p12" class="subbut"
 onclick="handleFree(['p10','p12']);"
 value="f0:=prefixRagits a" />
 <div id="ansp12"><div></div></div>

 <input type="submit" id="p13" class="subbut"
 onclick="handleFree(['p10','p13']);"
 value="f1:=cycleRagits a" />
 <div id="ansp13"><div></div></div>

```

You can construct any radix expansion by giving the whole, prefix, and cycle parts. The declaration is necessary to let Axiom know the base of the ragits.

```

 <input type="submit" id="p14" class="subbut"
 onclick="handleFree(['p11','p12','p13','p14']);"
 value="u:RadixExpansion(8):=wholeRadix(w)+fractRadix(f0,f1)" />
 <div id="ansp14"><div></div></div>

```

If there is no repeating part, then the list [0] should be used.

```

 <input type="submit" id="p15" class="subbut" onclick="makeRequest('p15');"
 value="v:RadixExpansion(12):=fractRadix([1,2,3,11],[0])" />
 <div id="ansp15"><div></div></div>

```

If you are not interested in the repeating nature of the expansion, an infinite stream of ragits can be obtained using

```

fractRagits

 <input type="submit" id="p16" class="subbut"
 onclick="handleFree(['p14','p16']);"

```

```

 value="fractRagits(u)" />
 <div id="ansp16"><div></div></div>

```

Of course, it's possible to recover the fraction representation:

```

 <input type="submit" id="p17" class="subbut"
 onclick="handleFree(['p10','p17']);"
 value="a::Fraction(Integer)" />
 <div id="ansp17"><div></div></div>

```

Issue the system command

```

 <input type="submit" id="p18" class="subbut"
 onclick="showcall('p18');"
 value=")show RadixExpansion"/>
 <div id="ansp18"><div></div></div>

```

to display the full list of operations defined by

[RadixExpansion](db.xhtml?RadixExpansion). More examples of expansions are available in

[DecimalExpansion](numrepeatingdecimals.xhtml),

[BinaryExpansion](numrepeatingbinaryexpansions.xhtml), and

[HexadecimalExpansion](numrepeatinghexexpansions.xhtml)

*<page foot>*

## 1.9.497 numpartialfractions.xhtml

```

<numpartialfractions.xhtml>≡
 <standard head>
 <script type="text/javascript">
 <handlefreevars>
 <axiom talker>
 </script>
 </head>
 <body onload="resetvars();">
 <page head>
 <div align="center">Partial Fractions</div>
 <hr/>

```

A partial fraction is a decomposition of a quotient into a sum of quotients where the denominators of the summand are powers of primes. (Most people first encounter partial fractions when they are learning integral calculus. For a technical discussion of partial fractions see, for example, Lang's Algebra.) For example, the rational number  $1/6$  is decomposed into  $1/2 - 1/3$ . You can compute partial fractions of quotients of objects from domains belonging to the category

```

EuclideanDomain. For example,
Integer,
Complex Integer, and

UnivariatePolynomial(x,Fraction Integer)

```

all belong to

```

EuclideanDomain.

```

In the examples following, we demonstrate how to decompose quotients of each of these kinds of objects into partial fractions.

It is necessary that we know how to factor the denominator when we want to compute a partial fraction. Although the interpreter can often do this automatically, it may be necessary for you to include a call to

```

factor. In these examples, it is not
necessary to factor the denominators explicitly. The main operation for
computing partial fractions is called

```

```

partialFraction and we use this
to compute a decomposition of $1/10!$. The first argument top
partialFraction is the numerator
of the quotient and the second argument is the factored denominator.

```

```

```

```

```

```

 <input type="submit" id="p1" class="subbut" onclick="makeRequest('p1');"
 value="partialFraction(1,factorial 10)" />

```

```

 <div id="ansp1"><div></div></div>

```

```

```

```

```

Since the denominators are powers of primes, it may be possible to expand the numerators further with respect to those primes. Use the operation [padicFraction](dboppadicfraction.xhtml) to do this.

```

```

```

```

```
<input type="submit" id="p2" class="subbut" onclick="makeRequest('p2');"
 value="f:=padicFraction(%)" />
```

```
<div id="ansp2"><div></div></div>
```

```

```

```

```

The operation [compactFraction](dbopcompactfraction.xhtml) returns an expanded fraction into the usual form. The compacted version is used internally for computational efficiency.

```

```

```

```

```
<input type="submit" id="p3" class="subbut"
 onclick="handleFree(['p2','p3']);"
 value="compactFraction(f)" />
```

```
<div id="ansp3"><div></div></div>
```

```

```

```

```

You can add, subtract, multiply, and divide partial fractions. In addition, you can extract the parts of the decomposition.

[numberOfFractionalTerms](dbopnumberoffractionalterms.xhtml)

computes the number of terms in the fractional part. This does not include the whole part of the fraction, which you get by calling

[wholePart](dbopwholepart.xhtml). In this example, the whole part is 0.

```

```

```

```

```
<input type="submit" id="p4" class="subbut"
 onclick="handleFree(['p2','p4']);"
 value="numberOfFractionalTerms(f)" />
```

```
<div id="ansp4"><div></div></div>
```

```

```

```

```

The operation

[nthFractionalTerm](dbopnthfractionalterm.xhtml)

returns the individual terms in the decomposition. Notice that the object returned is a partial fraction itself.

[firstNumer](dbopfirstnumer.xhtml) and

[firstDenom](dbopfirstdenom.xhtml) extract the numerator and denominator of the first term of the fraction.

```

```

```

```

```

<input type="submit" id="p5" class="subbut"
 onclick="handleFree(['p2','p5']);"
 value="nthFractionalTerm(f,3)" />
<div id="ansp5"><div></div></div>

```

Given two gaussian integers (see [Complex](db.xhtml?Complex)), you can decompose their quotient into a partial fraction.

```

 <input type="submit" id="p6" class="subbut" onclick="makeRequest('p6');"
 value="g:=partialFraction(1,-13+14*i)" />
 <div id="ansp6"><div></div></div>

```

To convert back to a quotient, simply use the conversion

```

 <input type="submit" id="p7" class="subbut"
 onclick="handleFree(['p6','p7']);"
 value="g::Fraction Complex Integer" />
 <div id="ansp7"><div></div></div>

```

To conclude this section, we compute the decomposition of

```

<pre>
 1

 2 3 4
 (x + 1)(x + 2) (a + 3) (x + 4)
</pre>

```

The polynomials in this object have type

```

UnivariatePolynomial(x,Fraction Integer).

```

We use the [primeFactor](dbopprimefactor.xhtml) operation (see [Factored](db.xhtml?Factored)) to create the denominator in factored form directly.

```

 <input type="submit" id="p8" class="subbut" onclick="makeRequest('p8');"
 value="u:FR UP(x,FRAC INT):=reduce(*,[primeFactor(x+i,i) for i in 1..4])"/>
 <div id="ansp8"><div></div></div>

```

These are the compact and expanded partial fractions for the quotient.

```

```

```

 <input type="submit" id="p9" class="subbut"
 onclick="handleFree(['p8','p9']);"
 value="pu:=partialFraction(1,u)" />
 <div id="ansp9"><div></div></div>

 <input type="submit" id="p10" class="subbut"
 onclick="handleFree(['p8','p9','p10']);"
 value="padicFraction pu" />
 <div id="ansp10"><div></div></div>

Also see

FullPartialFractionExpansion for examples of factor-free conversion of
quotients to full partial fractions.

Issue the system
command

 <input type="submit" id="p11" class="subbut"
 onclick="showcall('p11');"
 value=")show PartialFraction"/>
 <div id="ansp11"><div></div></div>

to display the full list of operations defined by
PartialFraction.

```

*<page foot>*

## 1.9.498 numproblems.xhtml

```

<numproblems.xhtml>≡
 <standard head>
 <script type="text/javascript">
 <handlefreevars>
 <axiom talker>
 </script>
 </head>
 <body>
 <page head>
 <div align="center">Problems</div>
 <hr/>
 One can show that if an integer of the form 2^{k-1} is prime then
 k must be prime.

 Proof
 Suppose that $k=m \cdot n$ is a non-trivial factorization. Then
 <pre>
 $2^m = 1 \pmod{2^{m-1}}$
 $2^{(m \cdot n)} = 1 \pmod{2^{m-1}}$
 so 2^{m-1} is a non-trivial factor of $2^k - 1$
 </pre>

 Problem Find the smallest prime p such that 2^{p-1} is not prime

 Answer

 First, define a function:

 <input type="submit" id="p1" class="noresult"
 onclick="makeRequest('p1');"
 value="f(n:NNI):INT == 2^n-1" />
 <div id="ansp1"><div></div></div>

 You can try factoring f(p) as p ranges through the set of primes.
 For example,

 <input type="submit" id="p2" class="subbut"
 onclick="handleFree(['p1','p2']);"
 value="factor f(7)" />
 <div id="ansp2"><div></div></div>

```

</ul>

This gets tedious after a while, so let's use Axiom's stream facility. A stream is essentially an infinite sequence. First, we create a stream consisting of the positive integers:

<ul>

<li>

```
<input type="submit" id="p3" class="subbut"
 onclick="makeRequest('p3');"
 value="ints:=[n for n in 1..]" />
```

```
<div id="ansp3"><div></div></div>
```

</li>

</ul>

Now, we create a stream consisting of the primes:

<ul>

<li>

```
<input type="submit" id="p4" class="subbut"
 onclick="handleFree(['p2','p4']);"
 value="primes:=[x for x in ints | prime? x]" />
```

```
<div id="ansp4"><div></div></div>
```

</li>

</ul>

Here is the 25th prime:

<ul>

<li>

```
<input type="submit" id="p5" class="subbut"
 onclick="handleFree(['p2','p5']);"
 value="primes.25" />
```

```
<div id="ansp5"><div></div></div>
```

</li>

</ul>

Next, create the stream of numbers of the form  $2^{p-1}$  with  $p$  prime:

<ul>

<li>

```
<input type="submit" id="p6" class="subbut"
 onclick="handleFree(['p1','p2','p3','p4','p6']);"
 value="numbers:=[f(n) for n in primes]" />
```

```
<div id="ansp6"><div></div></div>
```

</li>

</ul>

Finally, form the stream of factorizations of the elements of numbers:

<ul>

<li>

```
<input type="submit" id="p7" class="subbut"
 onclick="handleFree(['p1','p2','p3','p4','p6','p7']);"
 value="factors:=[factor n for n in numbers]" />
```

```
<div id="ansp7"><div></div></div>
```

```

```

You can see that the fifth number in the stream ( $2047=23 \cdot 89$ ) is the first one that has a non-trivial factorization. Since  $2^{11}=2048$ , the solution to the problem is 11.

Here is another way to see that 2047 is the first number in the stream that is composite:

```

 <input type="submit" id="p8" class="subbut"
 onclick="handleFree(['p3','p4','p6','p8']);"
 value="nums:=[x for x in numbers | not prime? x]" />
 <div id="ansp8"><div></div></div>

```

**Problem**: Find the smallest positive integer  $n$  such that  $n^2-n+41$  is not prime.

```

```

**Answer**: When  $n=41$ ,  $n^2-n+41=41^2$ , which certainly isn't prime. Is there any smaller integer that works? Here are the first 40 values:

```

 <input type="submit" id="p9" class="subbut"
 onclick="makeRequest('p9');"
 value="nums:=[n**2-n+41 for n in 0..40]" />
 <div id="ansp9"><div></div></div>

```

Now have Axiom factor the numbers on this list:

```

 <input type="submit" id="p10" class="subbut"
 onclick="handleFree(['p9','p10']);"
 value="[factor n for n in nums]" />
 <div id="ansp10"><div></div></div>

```

You can see that 41 is the smallest positive integer  $n$  such that  $n^2-n+41$  is not prime.

*<page foot>*

## 1.9.499 numquaternions.xhtml

*(numquaternions.xhtml)*≡

```

<standard head>
 <script type="text/javascript">
 <handlefreevars>
 <axiom talker>
 </script>
</head>
<body onload="resetvars();">
 <page head>
 <div align="center">Quaternions</div>
 <hr/>

```

The domain constructor `<a href="db.xhtml?Quaternion">Quaternion</a>` implements quaternions over commutative rings.

The basic operation for creating quaternions is

`<a href="dbopquatern.xhtml">quatern</a>`. This is a quaternion over the rational numbers.

```

 <input type="submit" id="p1" class="subbut" onclick="makeRequest('p1');"
 value="q:=quatern(2/11,-8,3/4,1)" />
 <div id="ansp1"><div></div></div>

```

The four arguments are the real part, the i imaginary part, the j imaginary part, and the k imaginary part, respectively.

```

 <input type="submit" id="p2" class="subbut"
 onclick="handleFree(['p1','p2']);"
 value="[real q, imagI q, imagJ q, imagK q]" />
 <div id="ansp2"><div></div></div>

```

Because q is over the rationals (and nonzero), you can invert it.

```

 <input type="submit" id="p3" class="subbut"
 onclick="handleFree(['p1','p3']);"
 value="inv q" />
 <div id="ansp3"><div></div></div>

```

The usual arithmetic (ring) operations are available.

```

 <input type="submit" id="p4" class="subbut"
 onclick="handleFree(['p1','p4']);"
 value="q^6" />
 <div id="ansp4"><div></div></div>

 <input type="submit" id="p5" class="subbut" onclick="makeRequest('p5');"
 value="r:=quatern(-2,3,23/9,-89)" />
 <div id="ansp5"><div></div></div>

 <input type="submit" id="p6" class="subbut"
 onclick="handleFree(['p1','p5','p6']);"
 value="q+r" />
 <div id="ansp6"><div></div></div>

```

In general, multiplication is not commutative.

```

 <input type="submit" id="p7" class="subbut"
 onclick="handleFree(['p1','p5','p7']);"
 value="q*r-r*q" />
 <div id="ansp7"><div></div></div>

```

There are no predefined constants for the imaginary  $i$ ,  $j$ , and  $k$  parts, but you can easily define them

```

 <input type="submit" id="p8" class="subbut" onclick="makeRequest('p8');"
 value="i:=quatern(0,1,0,0)" />
 <div id="ansp8"><div></div></div>

 <input type="submit" id="p9" class="subbut" onclick="makeRequest('p9');"
 value="j:=quatern(0,0,1,0)" />
 <div id="ansp9"><div></div></div>

 <input type="submit" id="p10" class="subbut" onclick="makeRequest('p10');"
 value="k:=quatern(0,0,0,1)" />
 <div id="ansp10"><div></div></div>

```

</ul>

These satisfy the normal identities.

<ul>

<li>

```
<input type="submit" id="p11" class="subbut"
 onclick="handleFree(['p1','p8','p9','p10','p11']);"
 value="[i*i,j*j,k*k,i*j,j*k,k*i,q*i]" />
<div id="ansp11"><div></div></div>
```

</li>

</ul>

The norm is the quaternion times its conjugate.

<ul>

<li>

```
<input type="submit" id="p12" class="subbut"
 onclick="handleFree(['p1','p12']);"
 value="norm q" />
<div id="ansp12"><div></div></div>
```

</li>

<li>

```
<input type="submit" id="p13" class="subbut"
 onclick="handleFree(['p1','p13']);"
 value="c:=conjugate q" />
<div id="ansp13"><div></div></div>
```

</li>

<li>

```
<input type="submit" id="p14" class="subbut"
 onclick="handleFree(['p1','p13','p14']);"
 value="q*c" />
<div id="ansp14"><div></div></div>
```

</li>

</ul>

For information on

related topics, see [Complex](db.xhtml?Complex) and

[Octonion](db.xhtml?Octonion). You can also issue the system command

<ul>

<li>

```
<input type="submit" id="p15" class="subbut"
 onclick="showcall('p15');"
 value=")show Quaternion"/>
<div id="ansp15"><div></div></div>

### 1.9.500 numquotientfields.xhtml

*(numquotientfields.xhtml)*≡

```

<standard head>
 <script type="text/javascript">
<handlefreevars>
<axiom talker>
 </script>
</head>
<body>
<page head>
 <div align="center">Quotient Fields</div>
 <hr/>

```

The [Fraction](db.xhtml?Fraction) domain implements quotients.

The elements must belong to a domain of category

[IntegralDomain](db.xhtml?IntegralDomain): multiplication must be commutative and the product of two non-zero elements must not be zero. This allows you to make fractions of most things you would think of, but don't expect to create a fraction of two matrices. The abbreviation for [Fraction](db.xhtml?Fraction) is [FRAC](db.xhtml?Fraction).

Use [</a>](dbopdivide.xhtml) to create a fraction.

```

 <input type="submit" id="p1" class="subbut"
 onclick="makeRequest('p1');"
 value="a:=11/12" />
 <div id="ansp1"><div></div></div>

 <input type="submit" id="p2" class="subbut"
 onclick="makeRequest('p2');"
 value="b:=23/24" />
 <div id="ansp2"><div></div></div>

```

The standard arithmetic operations are available.

```

 <input type="submit" id="p3" class="subbut"
 onclick="handleFree(['p1','p2','p3']);"
 value="3-a*b^2+a+b/a" />
 <div id="ansp3"><div></div></div>

```

Extract the numerator and denominator by using  
[numer](dbopnumber.xhtml) and [denom](dbopdenom.xhtml),  
 respectively.

```

 <input type="submit" id="p4" class="subbut"
 onclick="handleFree(['p1','p4']);"
 value="numer(a)" />
 <div id="ansp4"><div></div></div>

 <input type="submit" id="p5" class="subbut"
 onclick="handleFree(['p2','p5']);"
 value="denom(b)" />
 <div id="ansp5"><div></div></div>

```

Operations like

[max](dbopmax.xhtml), [min](dbopmin.xhtml),  
[negative?](dbopnegativeq.xhtml),  
[positive?](dboppositiveq.xhtml), and  
[zero?](dbopzeroq.xhtml) are all available if they are  
 provided for the numerators and denominators. See  
[Integer](numintegers.xhtml?Integer) for examples.

Don't expect a useful answer from

[factor](dbopfactor.xhtml),  
[gcd](dbopgcd.xhtml), or  
[lcm](dboplcm.xhtml) if you apply them to fractions.

```

 <input type="submit" id="p6" class="subbut"
 onclick="makeRequest('p6');"
 value="r:=(x^2+2*x+1)/(x^2-2*x+1)" />
 <div id="ansp6"><div></div></div>

```

Since all non-zero fractions are invertible, these operations have  
 trivial definitions.

```

 <input type="submit" id="p7" class="subbut"
 onclick="handleFree(['p6','p7']);"
 value="factor(r)" />
 <div id="ansp7"><div></div></div>

```

```

Use map to apply
factor to the numerator and denominator,
which is probably what you mean.

 <input type="submit" id="p8" class="subbut"
 onclick="handleFree(['p6','p8']);"
 value="map(factor,r)" />
 <div id="ansp8"><div></div></div>

```

Other forms of fractions are available, Use  
 <a href="dbopcontinuedfraction.xhtml">continuedFraction</a>  
 to create a continued fraction.

```

 <input type="submit" id="p9" class="subbut"
 onclick="makeRequest('p9');"
 value="continuedFraction(7/12)" />
 <div id="ansp9"><div></div></div>

```

Use <a href="dboppartialfraction.xhtml">partialFraction</a> to create a  
 partial fraction.

See <a href="numcontinuedfractions.xhtml">continuedFraction</a>  
 and <a href="numpartialfractions.xhtml">PartialFraction</a> for  
 additional information and examples.

```

 <input type="submit" id="p10" class="subbut"
 onclick="makeRequest('p10');"
 value="partialFraction(7,12)" />
 <div id="ansp10"><div></div></div>

```

Use conversion to create alternative views of fractions with objects  
 moved in and out of the numerator and denominator.

```

 <input type="submit" id="p11" class="subbut"
 onclick="makeRequest('p11');"
 value="g:=2/3+4/5*%i" />
 <div id="ansp11"><div></div></div>

```

```

Conversion is discussed in detail in
Conversion.

 <input type="submit" id="p12" class="subbut"
 onclick="handleFree(['p11','p12']);"
 value="g::FRAC COMPLEX INT" />
 <div id="ansp12"><div></div></div>

<page foot>
```

### 1.9.501 numrationalnumbers.xhtml

*(numrationalnumbers.xhtml)*  $\equiv$

```

<standard head>
 <script type="text/javascript">
 <handlefreevars>
 <axiom talker>
 </script>
</head>
<body>
 <page head>
 <div align="center">Rational Numbers</div>
 <hr/>

```

Like integers, rational numbers can be arbitrarily large. For example:

```

 <input type="submit" id="p1" class="subbut"
 onclick="makeRequest('p1');"
 value="61657^10/999983^12" />
 <div id="ansp1"><div></div></div>

```

Rational numbers will not be converted to decimals unless you explicitly ask Axiom to do so. To convert a rational number to a decimal, use the function [numeric](dbopnumeric.xhtml). Here's an example:

```

 <input type="submit" id="p2" class="subbut"
 onclick="makeRequest('p2');"
 value="x:=104348/33215" />
 <div id="ansp2"><div></div></div>

 <input type="submit" id="p3" class="subbut"
 onclick="handleFree(['p2','p3']);"
 value="numeric x" />
 <div id="ansp3"><div></div></div>

```

You can find the numerator and denominator of rational numbers using the functions [number](dbopnumber.xhtml) and [denom](dbopdenom.xhtml), respectively.

```

 <input type="submit" id="p4" class="subbut"
 onclick="handleFree(['p2','p4']);"

```

```

 value="numer(x)" />
 <div id="ansp4"><div></div></div>

 <input type="submit" id="p5" class="subbut"
 onclick="handleFree(['p2','p5']);"
 value="denom(x)" />
 <div id="ansp5"><div></div></div>

```

To factor the numerator and denominator of a fraction, use the following command:

```

 <input type="submit" id="p6" class="subbut"
 onclick="handleFree(['p2','p6']);"
 value="factor(numer x)/factor(denom x)" />
 <div id="ansp6"><div></div></div>

<page foot>

```

*<page foot>*

### 1.9.505 numromannumerals.xhtml

```

<numromannumerals.xhtml>≡
 <standard head>
 <script type="text/javascript">
 <handlefreevars>
 <axiom talker>
 </script>
 </head>
 <body onload="resetvars();">
 <page head>
 <div align="center">Roman Numerals</div>
 <hr/>

```

The Roman numeral package was added to Axiom in MCMLXXXVI for use in denoting higher order derivatives.

For example, let  $f$  be a symbolic operator.

```

 <input type="submit" id="p1" class="subbut" onclick="makeRequest('p1');"
 value="f:=operator 'f" />
 <div id="ansp1"><div></div></div>

```

This is the seventh derivative of  $f$  with respect to  $x$

```

 <input type="submit" id="p2" class="subbut" onclick="makeRequest('p2');"
 value="D(f x,x,7)" />
 <div id="ansp2"><div></div></div>

```

You can have integers printed as Roman numerals by declaring variables to be of type

```

RomanNumeral
(abbreviation ROMAN).

```

```

 <input type="submit" id="p3" class="subbut" onclick="makeRequest('p3');"
 value="a:=roman(1978-1965)" />
 <div id="ansp3"><div></div></div>

```

This package now has a small but devoted group of followers that claim this domain has shown its efficacy in many other contexts. They claim that Roman numerals are every bit as useful as ordinary integers.

In a sense, they are correct, because Roman numerals form a ring and you can therefore construct polynomials with Roman numeral coefficients, matrices over Roman numerals, etc..

```

 <input type="submit" id="p4" class="subbut" onclick="makeRequest('p4');"
 value="x:UTS(ROMAN,'x,0):=x" />
 <div id="ansp4"><div></div></div>

```

Was Fibonacci Italian or ROMAN?

```

 <input type="submit" id="p5" class="subbut"
 onclick="handleFree(['p4','p5']);"
 value="recip(1-x-x^2)" />
 <div id="ansp5"><div></div></div>

```

You can also construct fractions with Roman numeral numerators and denominators, as this matrix Hilberticus illustrates.

```

 <input type="submit" id="p6" class="subbut" onclick="makeRequest('p6');"
 value="m:MATRIX FRAC ROMAN" />
 <div id="ansp6"><div></div></div>

 <input type="submit" id="p7" class="subbut"
 onclick="handleFree(['p6','p7']);"
 value="m:=matrix [1/(i+j) for i in 1..3] for j in 1..3]" />
 <div id="ansp7"><div></div></div>

```

Note that the inverse of the matrix has integral  
[ROMAN](db.xhtml?RomanNumeral) entries.

```

 <input type="submit" id="p8" class="subbut"
 onclick="handleFree(['p6','p7','p8']);"
 value="inverse m" />
 <div id="ansp8"><div></div></div>

```

Unfortunately, the spoiler-sports say that the fun stops when the numbers get big -- mostly because the Romans didn't establish

conventions about representing very large numbers.

```

 <input type="submit" id="p9" class="subbut" onclick="makeRequest('p9');"
 value="y:=factorial 10" />
 <div id="ansp9"><div></div></div>

```

You work it out!

```

 <input type="submit" id="p10" class="subbut"
 onclick="handleFree(['p9','p10']);"
 value="roman y" />
 <div id="ansp10"><div></div></div>

```

Issue the system command

```

 <input type="submit" id="p11" class="subbut"
 onclick="showcall('p11');"
 value=")show RomanNumeral"/>
 <div id="ansp11"><div></div></div>

```

to display the full list of operations defined by  
[RomanNumeral](db.xhtml?RomanNumeral).

*<page foot>*

 Positive Definite Matrices $K=A'CA$

 One-dimensional Applications: A = Difference Matrix

 <page foot>
```

## 1.9.507 ocwmit18085lecture1.xhtml

```

<ocwmit18085lecture1.xhtml>≡
 <standard head>
 </head>
 <body>
 <page head>
 Positive Definite Matrices $K=A'CA$
 <hr/>
 In applied mathematics we have 2 basic tasks:

 Find the equations
 Solve the equations

 <h4>Positive Definite Matrices</h4>
 Certain matrices occur frequently in applied math. These three
 matrices (K,T,and M) are canonical examples.
 We have 3 3x3 matrices,
 <pre>
 K:Matrix(Integer):=[[2,-1,0],[-1,2,-1],[0,-1,2]]

 + 2 - 1 0 +
 | |
 |- 1 2 - 1|
 | |
 + 0 - 1 2 +
 Type: Matrix Integer
 T:Matrix(Integer):=[[1,-1,0],[-1,2,-1],[0,-1,2]]

 + 1 - 1 0 +
 | |
 |- 1 2 - 1|
 | |
 + 0 - 1 2 +
 Type: Matrix Integer
 B:Matrix(Integer):=[[1,-1,0],[-1,2,-1],[0,-1,1]]

 + 1 - 1 0 +
 | |
 |- 1 2 - 1|
 | |
 + 0 - 1 1 +
 Type: Matrix Integer
 </pre>
 These matrices are similar and can be generalized to square matrices
 of order N, with n x n elements. All of these matrices have the same

```

element along the diagonal. T (aka Top) differs from K in the first row. B (aka Both) differs from K in the first and last row. These represent different boundary conditions in the problem.

We can create K(n), T(n) and B(n) with the following commands:

```
<pre>
k(n) ==
 M := diagonalMatrix([2 for i in 1..n])
 for i in 1..n-1 repeat M(i,i+1):=-1
 for i in 1..n-1 repeat M(i+1,i):=-1
 M::SquareMatrix(n,Fraction(Integer))
</pre>
```

```
<pre>
t(n) ==
 M:=k(n)
 N:=M::Matrix(Fraction(Integer))
 qsetelt!(N,1,1,1)
 N::SquareMatrix(n,Fraction(Integer))
</pre>
```

```
<pre>
b(n) ==
 M:=k(n)
 N:=M::Matrix(Fraction(Integer))
 qsetelt!(N,1,1,1)
 qsetelt!(N,n,n,1)
 N::SquareMatrix(n,Fraction(Integer))
</pre>
```

K:=k(n) has a few key properties:

- <ul>
- <li> K is symmetric, that is  $K=K^T$ </li>
- <li> K might be nonsingular, that is, it is invertible</li>
- <li> K has a non-zero determinant</li>
- <li> K is banded (main diagonal and neighbors)</li>
- <li> K is tri-diagonal (main diagonal and nearest neighbors)</li>
- <li> K is extremely sparse</li>
- <li> K has constant diagonals, (shift invariant, time invariant)</li>
- <li> K is Toeplitz (constant diagonal, shows up in filters)</li>
- <li> K is good for Fourier analysis</li>
- </ul>

<h5>The inverse of T</h5>

If we look at the inverse of the T matrix we see:

```
<pre>
T^-1
```

```

+3 2 1+
| |
|2 2 1|
| |
+1 1 1+

```

```

Type: Matrix Fraction Integer

```

```

</pre>

```

Notice that these are all integers because the determinant of this matrix is 1

```

<pre>

```

```

determinant T

```

```

1

```

```

Type: Fraction Integer

```

```

</pre>

```

We can check that this matrix is the inverse of T.

When computing the inverse the row pattern [-1 2 -1] is a ‘‘second difference’’. The first column of the inverse matrix is [3 2 1] which is linear. When we take the second difference of a linear object we should get 0. Thus,

```

<pre>

```

```

[[-1,2,-1]]::MATRIX(INT)*[[3],[2],[1]]

```

```

[0]

```

```

Type: Matrix Integer

```

```

</pre>

```

The third column of the T matrix is linear and constant. If we take the second difference of that we also find it is zero:

```

<pre>

```

```

[[-1,2,-1]]::MATRIX(INT)*[[1],[1],[1]]

```

```

[0]

```

```

Type: Matrix Integer

```

```

</pre>

```

and the diagonal element of the unit matrix must be one. So the second difference of the second column is:

```

<pre>

```

```

[[-1,2,-1]]::MATRIX(INT)*[[2],[2],[1]]

```

```

[1]

```

```

Type: Matrix Integer

```

```

</pre>

```

So these simple checks show that we’re getting the correct

row and column values for the identity matrix by multiplying T times its inverse.

<br/>

<h5>The inverse of B</h5>

If we look for the inverse of the B matrix we can observe that the rows sum to zero which implies that it is not invertible. Thus it is singular.

K and T are positive definite. B is only positive semi-definite.

If we can find a vector that it takes to zero, that is if we can solve for x,y,z in:

<pre>

$$\begin{array}{ccccccc} + & 1 & & - & 1 & & 0 & + & + & x & + & & + & 0 & + \\ | & & & & & & | & | & & | & & | & & | & | \\ | & - & 1 & & 2 & & - & 1 & | & | & y & | & = & | & 0 & | \\ | & & & & & & | & | & & | & & | & & | & | \\ + & 0 & & - & 1 & & 1 & + & + & z & + & & + & 0 & + \end{array}$$

</pre>

The constant vector [1 1 1] solves this equation. When the rows sum to zero we are adding each row by a constant and thus we add each row times the constant one and we get zeros. If the matrix takes some vector to zero it cannot have an inverse since if

<pre>

$$B x = 0$$

</pre>

and x is not zero. If B had an inverse only x=0 would solve the equation. Since x=1 solves the equation B has no inverse. The vector x is in the nullspace of B. In fact any constant vector, e.g. [3 3 3] is in the nullspace. Thus the nullspace of B is cx for any constant c.

When doing matrix multiplication one way to think about the work is to consider the problem by columns. Thus in the multiplication

<pre>

$$\begin{array}{ccccccc} + & 1 & & - & 1 & & 0 & + & + & x & + & & + & 0 & + \\ | & & & & & & | & | & & | & & | & & | & | \\ | & - & 1 & & 2 & & - & 1 & | & | & y & | & = & | & 0 & | \\ | & & & & & & | & | & & | & & | & & | & | \\ + & 0 & & - & 1 & & 1 & + & + & z & + & & + & 0 & + \end{array}$$

</pre>

we can think about this as

```
<pre>
x*(first column) + y*(second column) + z*(third column).
</pre>
and for the constant vector [1 1 1] this means that we
just need to sum the columns.
```

Alternatively this can be computed by thinking of the multiplication as

```
<pre>
(first row)*(vector)
(second row)*(vector)
(third row)*(vector)
</pre>
```

<br/>

<h5>The inverse of K</h5>

Now we consider the K matrix we see the inverse

```
<pre>
```

K

```
+ 2 - 1 0 +
| |
|- 1 2 - 1|
| |
+ 0 - 1 2 +
```

Type: SquareMatrix(3,Fraction Integer)

```
kinv:=K^-1
```

```
+3 1 1+
|- - -|
|4 2 4|
| |
|1 1|
|- 1 -|
|2 2|
| |
|1 1 3|
|- - -|
+4 2 4+
```

Type: SquareMatrix(3,Fraction Integer)

```
</pre>
```

We can take the determinant of k

```
<pre>
```

```
determinant K
```

4

Type: Fraction Integer

&lt;/pre&gt;

Thus there is a constant 1/4 which can be factored out

&lt;pre&gt;

4\*kinv

```

+3 2 1+
| |
|2 4 2|
| |
+1 2 3+

```

Type: SquareMatrix(3,Fraction Integer)

&lt;/pre&gt;

Notice that the inverse is a symmetric matrix but not tri-diagonal. The inverse is not a sparse matrix so much more computation would be involved when using the inverse.

In order to solve the system

&lt;pre&gt;

K u = f

&lt;/pre&gt;

by elimination which implies multiplying and subtracting rows.

&lt;pre&gt;

$$K \quad u = f \quad ==> \quad U \quad u = f$$

&lt;/pre&gt;

For the 2x2 case we see:

&lt;pre&gt;

```

+2 -1+ +x+ +f1+ +2 -1+ + f1 +
| | | | = | | ==> | | | | = | |
| | | | | | | | | |
+-1 2+ +y+ +f2+ |0 -| +y+ |f2+-f1|
+ 2+ + 2 +

```

&lt;/pre&gt;

By multiplying row1 by 1/2 and adding it to row2 we create an upper triangular matrix U. Since we chose K(1,1), the number 2 is called the first pivot. K(2,2), the number 3/2, is called the second pivot.

For K 2x2 above is symmetric and invertible (since the pivots are all non-zero).

For the K 3x3 case the pivots are 2, 3/2, and 4/3. (The next pivots would be 5/4, 6/5, etc. for larger matrices).

For the T 3x3 case the pivots are 1, 1, and 1.

For the B 3x3 case the third pivot would be zero.

<hr/>

<h5>Generalizing the matrix pivot operations</h5>

For the 2x2 case we see construct an elimination matrix E which we can use to pre-multiply by K to give us the upper triangular matrix U

<pre>

$$E \quad K \quad = \quad U$$

</pre>

In detail we see

<pre>

$$\begin{array}{cc|cc|cc} +1 & 0 & + & & +2 & -1 & + \\ | & | & +2 & -1 & | & & | \\ |1 & | & | & & | & & 3| \\ |- & 1| & +-1 & 2+ & |0 & -| & \\ +2 & + & & & + & 2+ & \end{array}$$

</pre>

We wish to rewrite this as

<pre>

$$K = L U$$

</pre>

<hr/>

<h5>The big 4 solve operations in Linear Algebra</h5>

<ol>

<li>Elimination</li>

<li>Gram-Schmidt Orthogonalization</li>

<li>Eigenvalues</li>

<li>Singular Value Decomposition</li>

</ol>

Each of these operations is described by a factorization of K.

Elimination is written

<pre>

$$K = L U$$

</pre>

where L is lower triangular and U is upper triangular.

Thus we need a matrix L which when multiplied by U gives K.

The required matrix is the inverse of the E matrix above since

<pre>

$$1) \quad E K = \quad U$$

$$2) \quad E^{-1} E K = E^{-1} U$$

$$3) \quad I K = E^{-1} U$$

$$4) \quad \text{but } L = E^{-1}$$

$$5) \quad \text{so } K = L U$$

</pre>

Given the matrix operations above we had

<pre>

$$\begin{array}{cccc|cccc} E & & & & K & = & & U \\ \hline +1 & 0+ & & & +2 & -1+ & & \\ | & | & +2 & -1+ & | & & | & \\ |1 & | & | & & | & = & | & 3| \\ |- & 1| & +-1 & 2+ & |0 & -| & & \\ +2 & + & & & + & & 2+ & \end{array}$$

</pre>

and the inverse of E is the same matrix with a minus sign in the second row, thus:

<pre>

$$\begin{array}{cccc|cccc} & + & 1 & 0+ & & & & \\ -1 & | & & | & & & & \\ E & = & | & 1 & | & = & L & \\ & & |- & - & 1| & & & \\ & & + & 2 & + & & & \end{array}$$

</pre>

<hr/>

<h5>Making the matrices symmetric</h5>

We would like to preserve the symmetry property which we can do with a further decomposition of LU as follows:

<pre>

$$\begin{array}{cccc|cccc|cccc|cccc} L & & & & U & = & & L & & D & & U' \\ \hline + & 1 & 0+ & +2 & -1+ & & + & 1 & 0+ & +2 & 0+ & +1 & 1+ \\ | & & | & | & | & & | & & | & | & | & | & - & -| \\ | & 1 & | & | & 3| & = & | & 1 & | & | & 3| & | & 2| \\ |- & - & 1| & |0 & -| & & |- & - & 1| & |0 & -| & | & & | \\ + & 2 & + & + & 2+ & & + & 2 & + & + & 2+ & +0 & 1+ \end{array}$$

```
</pre>
```

So now we have 3 matrices; L is the lower triangular, D is symmetric and contains the pivots, and U' is upper triangular and is the transpose of the lower. So the real form we have is

```
<pre>
```

$$L^T D L$$

```
</pre>
```

This result will always be symmetric. We can check this by taking its transpose. If we get the same matrix we must have a symmetric matrix. So the transpose of

```
<pre>
```

$$(L^T D L)^T = L^T D^T L = L^T D L = L^T D L$$

```
</pre>
```

```
<hr/>
```

#### Positive Definite Matrices

There are several ways to recognize a positive definite matrix. First, it must be symmetric. The "positive" aspect comes from the pivots, all of which must be positive. Note that T is also positive definite. B is positive semi-definite because one of the pivots is zero. So

```
<pre>
```

```
positive definite == all pivots > 0
positive semi-definite == all pivots >= 0
```

```
</pre>
```

When all the pivots are positive then all the eigenvalues are positive.

So a positive definite matrix K and any non-zero vector X

```
<pre>
```

$$X^T K X > 0$$

```
</pre>
```

X transpose is just a row and X is just a column.

 <script type="text/javascript">
 <handlefreevars>
 <axiom talker>
 </script>
 </head>
 <body>
 <page head>
 <div align="center">Output Functions</div>
 <hr/>

```

A number of operations exist for specifying how numbers of type `<a href="db.xhtml?Float">Float</a>` are to be displayed. By default, spaces are inserted every ten digits in the output for readability. (Not that you cannot include spaces in the input form of a floating point number, though you can use underscores.)

Output spacing can be modified with the `<a href="dbopoutputspacing.xhtml">outputSpacing</a>` operation. This inserts no spaces and then displays the value of `x`.

```

 <input type="submit" id="p1" class="subbut"
 onclick="makeRequest('p1');"
 value="outputSpacing 0; x:=sqrt 0.2" />
 <div id="ansp1"><div></div></div>

```

Issue this to have the spaces inserted every 5 digits.

```

 <input type="submit" id="p2" class="subbut"
 onclick="handleFree(['p1','p2']);"
 value="outputSpacing 5; x" />
 <div id="ansp2"><div></div></div>

```

By default, the system displays floats in either fixed format or scientific format, depending on the magnitude of the number.

```

 <input type="submit" id="p3" class="subbut"
 onclick="handleFree(['p1','p3']);"
 value="y:=x/10^10" />

```

```

 <div id="ansp3"><div></div></div>

```

A particular format may be requested with the operations  
[outputFloating](dbopoutputfloating.xhtml) and  
[outputFixed](dbopoutputfixed.xhtml).

```

 <input type="submit" id="p4" class="subbut"
 onclick="handleFree(['p1','p4']);"
 value="outputFloating(); x" />
 <div id="ansp4"><div></div></div>

 <input type="submit" id="p5" class="subbut"
 onclick="handleFree(['p1','p5']);"
 value="outputFixed(); y" />
 <div id="ansp5"><div></div></div>

```

Additionally, you can ask for n digits to be displayed after the decimal point.

```

 <input type="submit" id="p6" class="subbut"
 onclick="handleFree(['p1','p3','p6']);"
 value="outputFloating 2; y" />
 <div id="ansp6"><div></div></div>

 <input type="submit" id="p7" class="subbut"
 onclick="handleFree(['p1','p7']);"
 value="outputFixed 2; x" />
 <div id="ansp7"><div></div></div>

```

The [outputGeneral](dbopoutputgeneral.xhtml) function resets the output printing to the default behavior.

```

 <input type="submit" id="p8" class="subbut"
 onclick="makeRequest('p8');"
 value="outputGeneral()" />
 <div id="ansp8"><div></div></div>

 <script type="text/javascript">
 <handlefreevars>
 <axiom talker>
 </script>
 </head>
 <body onload="resetvars();">
 <page head>
 <div align="center">TwoDimensionalArray</div>
 <hr/>

```

The `<a href="db.xhtml?TwoDimensionalArray">TwoDimensionalArray</a>` is used for storing data in a two-dimensional data structure indexed by row and column. Such an array is a homogeneous data structure in that all the entries of the array must belong to the same Axiom domain (although see `<a href="axbook/section-2.6.xhtml">The Any Domain</a>`). Each array has a fixed number of rows and columns specified by the user and arrays are not extensible. In Axiom, the indexing of two-dimensional arrays is one-based. This means that both the "first" row of an array and the "first" column of an array are given the index 1. Thus, the entry in the upper left corner of an array is in position (1,1).

The operation `<a href="dbopnew.xhtml">new</a>` creates an array with a specified number of rows and columns and fills the components of that array with a specified entry. The arguments of this operation specify the number of rows, the number of columns, and the entry. This creates a five-by-four array of integers, all of whose entries are zero.

```

 <input type="submit" id="p1" class="subbut"
 onclick="makeRequest('p1');"
 value="arr:ARRAY2 INT:=new(5,4,0)" />
 <div id="ansp1"><div></div></div>

```

The entries of this array can be set to other integers using the operation `<a href="dbopsetelt.xhtml">setelt</a>`.

Issue this to set the element in the upper left corner of this array to 17.

```

 <input type="submit" id="p2" class="subbut"
 onclick="handleFree(['p1','p2']);"
 value="setelt(arr,1,1,17)" />

```

```

 <div id="ansp2"><div></div></div>

Now the first element of the array is 17.

 <input type="submit" id="p3" class="subbut"
 onclick="handleFree(['p1','p2','p3']);"
 value="arr" />
 <div id="ansp3"><div></div></div>

```

Likewise, elements of an array are extracted using the operation  
[elt](dbopelt.xhtml).

```

 <input type="submit" id="p4" class="subbut"
 onclick="handleFree(['p1','p2','p4']);"
 value="elt(arr,1,1)" />
 <div id="ansp4"><div></div></div>

```

Another way to use these two operations is as follows. This sets the  
 element in position (3,2) of the array to 15.

```

 <input type="submit" id="p5" class="subbut"
 onclick="handleFree(['p1','p2','p5']);"
 value="arr(3,2):=15" />
 <div id="ansp5"><div></div></div>

```

This extracts the element in position (3,2) of the array.

```

 <input type="submit" id="p6" class="subbut"
 onclick="handleFree(['p1','p2','p5','p6']);"
 value="arr(3,2)" />
 <div id="ansp6"><div></div></div>

```

The operation [elt](dbopelt.xhtml) and  
[setelt](dbopsetelt.xhtml) come equipped with an error check  
 which verifies that the indices are in the proper ranges. For example,  
 the above array has five rows and four columns, so if you ask for the  
 entry in position (6,2) with `arr(6,2)` Axiom displays an error message.

If there is no need for an error check, you can call the operations `<a href="dbopqelt.xhtml">qelt</a>` and `<a href="dbopqseteltbang.xhtml">qsetelt!</a>` which provide the same functionality but without the error check. Typically, these operations are called in well-tested programs.

The operations `<a href="dboprow.xhtml">row</a>` and `<a href="dbopcolumn.xhtml">column</a>` extract rows and columns, respectively, and return objects of `<a href="db.xhtml?OneDimensionalArray">OneDimensionalArray</a>` with the same underlying element type.

```

 <input type="submit" id="p7" class="subbut"
 onclick="handleFree(['p1','p2','p5','p7']);"
 value="row(arr,1)" />
 <div id="ansp7"><div></div></div>

 <input type="submit" id="p8" class="subbut"
 onclick="handleFree(['p1','p2','p5','p8']);"
 value="column(arr,1)" />
 <div id="ansp8"><div></div></div>

```

You can determine the dimensions of an array by calling the operations `<a href="dbopnrows.xhtml">nrows</a>` and `<a href="dbopncols.xhtml">ncols</a>`, which return the number of rows and columns, respectively.

```

 <input type="submit" id="p9" class="subbut"
 onclick="handleFree(['p1','p2','p5','p9']);"
 value="nrows(arr)" />
 <div id="ansp9"><div></div></div>

 <input type="submit" id="p10" class="subbut"
 onclick="handleFree(['p1','p2','p5','p10']);"
 value="ncols(arr)" />
 <div id="ansp10"><div></div></div>

```

To apply an operation to every element of an array, use `<a href="dbopmap.xhtml">map</a>`. This creates a new array. This

expression negates every element.

```

 <input type="submit" id="p11" class="subbut"
 onclick="handleFree(['p1','p2','p5','p11']);"
 value="map(-,arr)" />
 <div id="ansp11"><div></div></div>

```

This creates an array where all the elements are doubled.

```

 <input type="submit" id="p12" class="subbut"
 onclick="handleFree(['p1','p2','p5','p11','p12']);"
 value="map((x+>x+x),arr)" />
 <div id="ansp12"><div></div></div>

```

To change the array destructively, use

[map!](dbopmapbang.xhtml) instead of  
[map](dbopmap.xhtml).

If you need to make a copy of an array,  
 use [copy](dbopcopy.xhtml).

```

 <input type="submit" id="p13" class="subbut"
 onclick="handleFree(['p1','p2','p5','p11','p12','p13']);"
 value="arrc:=copy(arr)" />
 <div id="ansp13"><div></div></div>

 <input type="submit" id="p14" class="subbut"
 onclick="handleFree(['p1','p2','p5','p11','p12','p13','p14']);"
 value="map!(-,arrc)" />
 <div id="ansp14"><div></div></div>

 <input type="submit" id="p15" class="subbut"
 onclick="handleFree(['p1','p2','p5','p11','p12','p13','p14','p15']);"
 value="arrc" />
 <div id="ansp15"><div></div></div>

 <input type="submit" id="p16" class="subbut"
 onclick="handleFree(['p1','p2','p5','p11','p12','p16']);"
 value="arr" />
```

```

 <div id="ansp16"><div></div></div>

```

Use [member?](dbopmemberq.xhtml) to see if a given element is in an array.

```

 <input type="submit" id="p17" class="subbut"
 onclick="handleFree(['p1','p2','p5','p11','p12','p17']);"
 value="member?(17,arr)" />
 <div id="ansp17"><div></div></div>

 <input type="submit" id="p18" class="subbut"
 onclick="handleFree(['p1','p2','p5','p11','p12','p18']);"
 value="member?(10317,arr)" />
 <div id="ansp18"><div></div></div>

```

To see how many times an element appears in an array, use [count](dbopcount.xhtml).

```

 <input type="submit" id="p19" class="subbut"
 onclick="handleFree(['p1','p2','p5','p11','p12','p19']);"
 value="count(17,arr)" />
 <div id="ansp19"><div></div></div>

 <input type="submit" id="p20" class="subbut"
 onclick="handleFree(['p1','p2','p5','p11','p12','p20']);"
 value="count(0,arr)" />
 <div id="ansp20"><div></div></div>

```

For more information about the operations available for [TwoDimensionalArray](db.xhtml?TwoDimensionalArray), issue

```

 <input type="submit" id="p21" class="subbut"
 onclick="showcall('p21');"
 value=")show TwoDimensionalArray"/>
 <div id="ansp21"><div></div></div>

```

For more information on related topics, see

```
Matrix and
OneDimensionalArray.
⟨page foot⟩
```

### 1.9.519 pagevector.xhtml

```
⟨pagevector.xhtml⟩≡
 ⟨standard head⟩
 </head>
 <body>
 ⟨page head⟩
 pagevector not implemented
 ⟨page foot⟩
```

### 1.9.520 polybasicfunctions.xhtml

```

<polybasicfunctions.xhtml>≡
 <standard head>
 <script type="text/javascript">
 <handlefreevars>
 <axiom talker>
 </script>
 </head>
 <body onload="resetvars();">
 <page head>
 <div align="center">Basic Operations on Polynomials</div>
 <hr/>

```

You create polynomials using the usual operations of

```

+,
-,
*
(for multiplication), and
* (or
^. Here are two examples:

```

```

 <input type="submit" id="p1" class="subbut"
 onclick="makeRequest('p1');"
 value="p:=a*x**2+b*x*y+c*y**2" />
 <div id="ansp1"><div></div></div>

 <input type="submit" id="p2" class="subbut"
 onclick="makeRequest('p2');"
 value="q:=12*x^2+3*z" />
 <div id="ansp2"><div></div></div>

```

These operations can also be used to combine polynomials. Try the following:

```

 <input type="submit" id="p3" class="subbut"
 onclick="handleFree(['p1','p2','p3']);"
 value="p+q" />
 <div id="ansp3"><div></div></div>

 <input type="submit" id="p4" class="subbut"
 onclick="handleFree(['p1','p2','p4']);"
 value="p-3*q" />

```

```

 <div id="ansp4"><div></div></div>

 <input type="submit" id="p5" class="subbut"
 onclick="handleFree(['p1','p2','p5']);"
 value="p**2+p*q" />
 <div id="ansp5"><div></div></div>

 <input type="submit" id="p6" class="subbut"
 onclick="handleFree(['p1','p2','p6']);"
 value="r:=(p+q)**2" />
 <div id="ansp6"><div></div></div>

```

As you can see from the above examples, the variables are ordered by defaults

```

<pre>
 z > y > x > c > b > a
</pre>

```

That is, z is the main variable, then y and so on in reverse alphabetical order. You can redefine this ordering (for display purposes) with the [setVariableOrder](dbopsetvariableorder.xhtml). For example, the following makes a the main variable, then b, and so on:

```

 <input type="submit" id="p7" class="subbut"
 onclick="makeRequest('p7');"
 value="setVariableOrder [a,b,c,x,y,z]" />
 <div id="ansp7"><div></div></div>

```

Now compare the way polynomials are displayed:

```

 <input type="submit" id="p8" class="subbut"
 onclick="handleFree(['p1','p7','p8']);"
 value="p" />
 <div id="ansp8"><div></div></div>

 <input type="submit" id="p9" class="subbut"
 onclick="handleFree(['p2','p7','p9']);"
 value="q" />
 <div id="ansp9"><div></div></div>

```

```

<div></div></div>

To return to the system's default ordering, use
resetVariableOrder.

<div></div></div>

<div></div></div>

Polynomial coefficients can be pulled out using the function
coefficient. For example:

<div></div></div>

will give you the coefficient of x^2 in the polynomial q . Try these
commands:

<div></div></div>

<div></div></div>

```

```

 <input type="submit" id="p16" class="subbut"
 onclick="handleFree(['p6','p15','p16']);"
 value="coefficient(c,x,2)" />
 <div id="ansp16"><div></div></div>

```

Coefficients of monomials can be obtained as follows:

```

 <input type="submit" id="p17" class="subbut"
 onclick="handleFree(['p2','p17']);"
 value="coefficient(q**2,[x,z],[2,1])" />
 <div id="ansp17"><div></div></div>

```

This will return the coefficient of  $x^{**2}z$  in the polynomial  $q^{**2}$ . Also,

```

 <input type="submit" id="p18" class="subbut"
 onclick="handleFree(['p1','p2','p6','p18']);"
 value="coefficient(r,[x,y],[2,2])" />
 <div id="ansp18"><div></div></div>

```

will return the coefficient of  $x^{**2}y^{**2}$  in the polynomial  $r(x,y)$ .

*<page foot>*

### 1.9.521 polyfactorization.xhtml

 <div id="ansp8"><div></div></div>

```

Factor again over the field obtained by adjoining both aa and bb to the rational numbers.

```

 <input type="submit" id="p9" class="subbut"
 onclick="handleFree(['p1','p7','p9']);"
 value="factor(x^6+108,[aa,bb])" />
 <div id="ansp9"><div></div></div>

```

*<page foot>*

## 1.9.525 polyfactorization4.xhtml

*<polyfactorization4.xhtml>*≡

*<standard head>*

`<script type="text/javascript">`

*<handlefreevars>*

*<axiom talker>*

`</script>`

`</head>`

`<body onload="resetvars();">`

*<page head>*

`<div align="center">Factoring Rational Functions</div>`

`<hr/>`

Since fractions of polynomials form a field, every element (other than zero) divides any other, so there is no useful notion of irreducible factors.

Thus the `<a href="dbopfactor.xhtml">factor</a>` operation is not very useful for fractions of polynomials.

Instead, there is a specific operation

`<a href="dbopfactorfraction.xhtml">factorFraction</a>` that separately factors the numerator and denominator and returns a fraction of the factored results.

`<ul>`

`<li>`

`<input type="submit" id="p1" class="subbut"
onclick="makeRequest('p1');"
value="factorFraction((x^2-4)/(y^2-4))" />
<div id="ansp1"><div></div></div>`

`</li>`

`</ul>`

You can also use `<a href="dbopmap.xhtml">map</a>`. This expression applies the `<a href="dbopfactor.xhtml">factor</a>` operation to the numerator and denominator.

`<ul>`

`<li>`

`<input type="submit" id="p2" class="subbut"
onclick="makeRequest('p2');"
value="map(factor,(x^2-4)/(y^2-4))" />
<div id="ansp2"><div></div></div>`

`</li>`

`</ul>`

*<page foot>*

### 1.9.526 polygcdandfriends.xhtml

*(polygcdandfriends.xhtml)*≡

```

<standard head>
 <script type="text/javascript">
 <handlefreevars>
 <axiom talker>
 </script>
</head>
<body onload="resetvars();">
 <page head>
 <div align="center">
 Greatest Common Divisors, Resultants, and Discriminants
 </div>
 <hr/>

```

You can compute the greatest common divisor of two polynomials using the function `<a href="dbopgcd.xhtml">gcd</a>`. Here's an example:

```

 <input type="submit" id="p1" class="subbut"
 onclick="makeRequest('p1');"
 value="p:=3*x^8+2*x^7+6*x^2+7*x+2" />
 <div id="ansp1"><div></div></div>

 <input type="submit" id="p2" class="subbut"
 onclick="makeRequest('p2');"
 value="q:=2*x^13+9*x^7+2*x^6+10*x+5" />
 <div id="ansp2"><div></div></div>

 <input type="submit" id="p3" class="subbut"
 onclick="handleFree(['p1','p2','p3']);"
 value="gcd(p,q)" />
 <div id="ansp3"><div></div></div>

```

You could also see that  $p$  and  $q$  have a factor in common by using the function `<a href="dbopresultant.xhtml">resultant</a>`:

```

 <input type="submit" id="p4" class="subbut"
 onclick="handleFree(['p1','p2','p4']);"
 value="resultant(p,q,x)" />
 <div id="ansp4"><div></div></div>

```

</ul>

The resultant of two polynomials vanishes precisely when they have a factor in common. (In the example above we specified the variable with which we wanted to compute the resultant because the polynomials could have involved variables other than  $x$ .)

*<page foot>*

 onclick="handleFree(['p1','p5']);"
 value="definingPolynomial %x2" />
 <div id="ansp5"><div></div></div>

```

We can check that the sum and product of the roots of  $x^4+1$  are its trace and norm.

```

 <input type="submit" id="p6" class="subbut"
 onclick="handleFree(['p1','p6']);"
 value="x3:=last l" />
 <div id="ansp6"><div></div></div>

 <input type="submit" id="p7" class="subbut"
 onclick="handleFree(['p1','p6','p7']);"
 value="%x0+%x1+%x2+x3" />
 <div id="ansp7"><div></div></div>

 <input type="submit" id="p8" class="subbut"
 onclick="handleFree(['p1','p6','p8']);"
 value="%x0*%x1*%x2*x3" />
 <div id="ansp8"><div></div></div>

```

Corresponding to the pair of operations

[rootOf](dboprootof.xhtml) and

[zeroOf](dbopzeroof.xhtml) in

<axbook/section-8.5.xhtml#subsec-8.5.2>

Solution of a Single Polynomial Equation

there is an operations [zerosOf](dbopzerosof.xhtml) that, like [rootsOf](dboprootof.xhtml), computes all the roots of a given polynomial, but which expresses some of them in terms of radicals.

```

```

```

<input type="submit" id="p9" class="subbut"
 onclick="makeRequest('p9');"
 value="zerosOf(y^4+1,y)" />
<div id="ansp9"><div></div></div>

```

As you see, only one implicit algebraic number was created (%y1), and its defining equation is this. The other three roots are expressed in radicals.

```

 <input type="submit" id="p10" class="subbut"
 onclick="handleFree(['p9','p10']);"
 value="definingPolynomial %y1" />
 <div id="ansp10"><div></div></div>

```

*<page foot>*

**1.9.531 polyroots3.xhtml**

```

<polyroots3.xhtml>≡
 <standard head>
 <script type="text/javascript">
 <handlefreevars>
 <axiom talker>
 </script>
 </head>
 <body onload="resetvars();">
 <page head>
 <div align="center">Solution of a Single Polynomial Equation</div>
 <hr/>

```

Axiom can solve polynomial equations producing either approximate or exact solutions. Exact solutions are either members of the ground field or can be presented symbolically as roots of irreducible polynomials.

This returns one rational root along with an irreducible polynomial describing the other solutions

```

 <input type="submit" id="p1" class="subbut"
 onclick="makeRequest('p1');"
 value="solve(x^3=8,x)" />
 <div id="ansp1"><div></div></div>

```

If you want solutions expressed in terms of radicals you would use this instead.

```

 <input type="submit" id="p2" class="subbut"
 onclick="makeRequest('p2');"
 value="radicalSolve(x^3=8,x)" />
 <div id="ansp2"><div></div></div>

```

The [solve](dbopsolve.xhtml) command always returns a value but [radicalSolve](dbopradicalsolve.xhtml) returns only the solutions that it is able to express in terms of radicals.

If the polynomial equation has rational coefficients you can ask for approximations to its real roots by calling solve with a second argument that specifies the "precision" epsilon. This means that each approximation will be within plus or minus epsilon of the actual result.

Notice that the type of second argument controls the type of the result.

```

 <input type="submit" id="p3" class="subbut"
 onclick="makeRequest('p3');"
 value="solve(x^4-10*x^3+35*x^2-50*x+25,.0001)" />
 <div id="ansp3"><div></div></div>

```

If you give a floating point precision you get a floating point result.

If you give the precision as a ration number you get a rational result.

```

 <input type="submit" id="p4" class="subbut"
 onclick="makeRequest('p4');"
 value="solve(x^2-2,1/1000)" />
 <div id="ansp4"><div></div></div>

```

If you want approximate complex results you should use the command  
[complexSolve](dbopcomplexsolve.xhtml) that takes the same  
 precision argument epsilon.

```

 <input type="submit" id="p5" class="subbut"
 onclick="makeRequest('p5');"
 value="complexSolve(x^3-2,.0001)" />
 <div id="ansp5"><div></div></div>

```

Each approximation will be within plus or minus epsilon of the actual result  
 in each of the real and imaginary parts.

```

 <input type="submit" id="p6" class="subbut"
 onclick="makeRequest('p6');"
 value="complexSolve(x^2-2*i+1,1/100)" />
 <div id="ansp6"><div></div></div>

```

Note that if you omit the = from the first argument Axiom generates  
 an equation by equating the first argument to zero. Also, when only one  
 variable is present in the equation, you do not need to specify the  
 variable to be solved for, that is, you can omit the second argument.

Axiom can also solve equations involving rational functions. Solutions

where the denominator vanishes are discarded.

<ul>

<li>

<input type="submit" id="p7" class="subbut"  
onclick="makeRequest('p7');"

value="radicalSolve(1/x^3+1/x^2+1/x=0,x)" />

<div id="ansp7"><div></div></div>

</li>

</ul>

<page foot>

### 1.9.532 polyroots4.xhtml

```

<polyroots4.xhtml>≡
 <standard head>
 <script type="text/javascript">
 <handlefreevars>
 <axiom talker>
 </script>
 </head>
 <body onload="resetvars();">
 <page head>
 <div align="center">Solution of Systems of Polynomial Equations</div>
 <hr/>
 Given a system of equations of rational functions with exact coefficients
 <pre>
 p1(x1,...,xn)
 .
 .
 pm(x1,...,xn)
 </pre>
 Axiom can find numeric or symbolic solutions. The system is first split
 into irreducible components, then for each component, a triangular system
 of equations is found that reduces the problem to sequential solutions of
 univariate polynomials resulting from substitution of partial solutions
 from the previous stage.
 <pre>
 q1(x1,...,xn)
 .
 .
 qm(xn)
 </pre>
 Symbolic solutions can be presented using "implicit" algebraic numbers
 defined as roots of irreducible polynomials or in terms of radicals. Axiom
 can also find approximations to the real or complex roots of a system of
 polynomial equations to any user specified accuracy.

 The operation solve for systems is used in
 a way similar to solve for single equations.
 Instead of a polynomial equation, one has to give a list of equations and
 instead of a single variable to solve for, a list of variables. For
 solutions of single equations see

 Solution of a Single Polynomial Equation

 Use the operation solve if you want
 implicitly presented solutions.

```

```

 <input type="submit" id="p1" class="subbut"
 onclick="makeRequest('p1');"
 value="solve([3*x^2+y+1,y^2-4],[x,y])" />
 <div id="ansp1"><div></div></div>

 <input type="submit" id="p2" class="subbut"
 onclick="makeRequest('p2');"
 value="solve([x=y^2-19,y=z^2+x+3,z=3*x],[x,y,z])" />
 <div id="ansp2"><div></div></div>

```

Use [radicalSolve](dbopradialsolve.xhtml) if you want your solutions expressed in terms of radicals.

```

 <input type="submit" id="p3" class="subbut"
 onclick="makeRequest('p3');"
 value="radicalSolve([3*x^3+y+1,y^2-4],[x,y])" />
 <div id="ansp3"><div></div></div>

```

To get numeric solutions you only need to give the list of equations and the precision desired. The list of variables would be redundant information since there can be no parameters for the numerical solver.

If the precision is expressed as a floating point number you get results expressed as floats.

```

 <input type="submit" id="p4" class="subbut"
 onclick="makeRequest('p4');"
 value="solve([x^2*y-1,x*y^2-2],.01)" />
 <div id="ansp4"><div></div></div>

```

To get complex numeric solutions, use the operation

[complexSolve](dbopcomplexsolve.xhtml), which takes the same arguments as in the real case.

```

 <input type="submit" id="p5" class="subbut"
 onclick="makeRequest('p5');"
 value="complexSolve([x^2*y-1,x*y^2-2],1/1000)" />

```

```

 <div id="ansp5"><div></div></div>

```

It is also possible to solve systems of equations in rational functions over the rational numbers. Note that  $[x=0.0, a=0.0]$  is not returned as a solution since the denominator vanishes there.

```

 <input type="submit" id="p6" class="subbut"
 onclick="makeRequest('p6');"
 value="solve([x^2/a=a,a=a*x],.001)" />
 <div id="ansp6"><div></div></div>

```

When solving equations with denominators, all solutions where the denominator vanishes are discarded.

```

 <input type="submit" id="p7" class="subbut"
 onclick="makeRequest('p7');"
 value="radicalSolve([x^2/a+a*y^3-1,a*y+a+1],[x,y])" />
 <div id="ansp7"><div></div></div>

<page foot>

```

**1.9.533 polyspecifictypes.xhtml**

```

### 1.9.534 polyspecifictypes1.xhtml

*(polyspecifictypes1.xhtml)≡*

```

<standard head>
 <script type="text/javascript">
 <handlefreevars>
 <axiom talker>
 </script>
</head>
<body onload="resetvars();">
 <page head>
 <div align="center">Polynomial</div>
 <hr/>

```

The domain constructor `<a href="db.xhtml?Polynomial">Polynomial</a>` (abbreviation: `<a href="db.xhtml?Polynomial">POLY</a>`) provides polynomials with an arbitrary number of unspecified variables.

It is used to create the default polynomial domains in Axiom. Here the coefficients are integers.

```

 <input type="submit" id="p1" class="subbut"
 onclick="makeRequest('p1');"
 value="x+1" />
 <div id="ansp1"><div></div></div>

```

Here the coefficients have type `<a href="db.xhtml?Float">Float</a>`.

```

 <input type="submit" id="p2" class="subbut"
 onclick="makeRequest('p2');"
 value="z-2.3" />
 <div id="ansp2"><div></div></div>

```

And here we have a polynomial in two variables with coefficients which have type `<a href="dbfractioninteger.xhtml">Fraction Integer</a>`

```

 <input type="submit" id="p3" class="subbut"
 onclick="makeRequest('p3');"
 value="y^2-z+3/4" />
 <div id="ansp3"><div></div></div>

```

The representation of objects of domains created by `<a href="db.xhtml?Polynomial">Polynomial</a>` is that of recursive univariate polynomials. (The term univariate means "one variable". The term multivariate means "possibly more than one variable".) This recursive structure is sometimes obvious from the display of a polynomial.

```

 <input type="submit" id="p4" class="subbut"
 onclick="makeRequest('p4');"
 value="r:=y^2+x*y+y" />
 <div id="ansp4"><div></div></div>

```

In this example, you see that the polynomial is stored as a polynomial in  $y$  with coefficients that are polynomials in  $x$  with integer coefficients. In fact, you really don't need to worry about the representation unless you are working on an advanced application where it is critical. The polynomial types created from

```

DistributedMultivariatePolynomial and
XDistributedPolynomial
(discussed in
"DistributedMultivariatePolynomial"
are stored and displayed in a
non-recursive manner. You see a "flat" display of the above polynomial by
converting to one of those types.
```

```

 <input type="submit" id="p5" class="subbut"
 onclick="handleFree(['p4','p5']);"
 value="r::DMP([y,x],INT)" />
 <div id="ansp5"><div></div></div>

```

We will demonstrate many of the polynomial facilities by using two polynomials with integer coefficients. By default, the interpreter expands polynomial expressions, even if they are written in a factored format.

```

 <input type="submit" id="p6" class="subbut"
 onclick="makeRequest('p6');"
 value="p:=(y-1)^2*x*z" />
 <div id="ansp6"><div></div></div>

```

See <axbook/section-9.22.xhtml> Factored

to see how to create objects in factored form directly.

```

 <input type="submit" id="p7" class="subbut"
 onclick="makeRequest('p7');"
 value="q:=(y-1)*x*(z+5)" />
 <div id="ansp7"><div></div></div>

```

The fully factored form can be recovered by using

<dbopfactor.xhtml> factor

```

 <input type="submit" id="p8" class="subbut"
 onclick="handleFree(['p7','p8']);"
 value="factor(q)" />
 <div id="ansp8"><div></div></div>

```

This is the same name used for the operation to factor integer.

Such reuse of names is called

[overloading](glossarypage.xhtml#p36465) and makes it much easier to think of solving problems in general ways. Axiom facilities for factoring polynomials created with

[Polynomial](db.xhtml?Polynomial)

are currently restricted to the integer and rational number coefficients cases. There are more complete facilities for factoring univariate polynomials (see

[Polynomial Factorization](axbook/section-8.2.xhtml))

The standard arithmetic operations are available for polynomials.

```

 <input type="submit" id="p9" class="subbut"
 onclick="handleFree(['p6','p7','p9']);"
 value="p-q^2" />
 <div id="ansp9"><div></div></div>

```

The operation [gcd](dbopgcd.xhtml) is used to compute the greatest common divisor of two polynomials.

```

 <input type="submit" id="p10" class="subbut"
 onclick="handleFree(['p6','p7','p10']);"
```

```

 value="m:=gcd(p,q)" />
 <div id="ansp10"><div></div></div>

```

In the case of  $p$  and  $q$ , the gcd is obvious from their definitions. We factor the gcd to show this relationship better.

```

 <input type="submit" id="p11" class="subbut"
 onclick="handleFree(['p6','p7','p10','p11']);"
 value="factor m" />
 <div id="ansp11"><div></div></div>

```

The least common multiple is computed by using

[lcm](dboplcm.xhtml).

```

 <input type="submit" id="p12" class="subbut"
 onclick="handleFree(['p6','p7','p12']);"
 value="lcm(p,q)" />
 <div id="ansp12"><div></div></div>

```

Use [content](dbopcontent.xhtml) to compute the greatest common divisor of the coefficients of the polynomial.

```

 <input type="submit" id="p13" class="subbut"
 onclick="handleFree(['p6','p13']);"
 value="content p" />
 <div id="ansp13"><div></div></div>

```

Many of the operations on polynomials require you to specify a variable. For example, [resultant](dbopresultant.xhtml) requires you to give the variable in which the polynomials should be expressed. This computes the resultant of the values of  $p$  and  $q$ , considering them as polynomials in the variable  $z$ . They do not share a root when thought of as polynomials in  $z$ .

```

 <input type="submit" id="p14" class="subbut"
 onclick="handleFree(['p6','p7','p14']);"
 value="resultant(p,q,z)" />
 <div id="ansp14"><div></div></div>

```

```

```

```

```

This value is 0 because as polynomials in  $x$  the polynomials have a common root.

```

```

```

```

```
<input type="submit" id="p15" class="subbut"
 onclick="handleFree(['p6','p7','p15']);"
 value="resultant(p,q,x)" />
```

```
<div id="ansp15"><div></div></div>
```

```

```

```

```

The data type used for the variables created by

[Polynomial](db.xhtml?Polynomial) is

[Symbol](db.xhtml?Symbol). As mentioned above, the representation used by [Polynomial](db.xhtml?Polynomial) is recursive and so there is a main variable for nonconstant polynomials. The operation [makeVariable](dbopmainvariable.xhtml) returns this variable. The return type is actually a union of [Symbol](db.xhtml?Symbol) and "failed".

```

```

```

```

```
<input type="submit" id="p16" class="subbut"
 onclick="handleFree(['p6','p16']);"
 value="mainVariable p" />
```

```
<div id="ansp16"><div></div></div>
```

```

```

```

```

The latter branch of the union is used if the polynomial has no variables, that is, is a constant.

```

```

```

```

```
<input type="submit" id="p17" class="subbut"
 onclick="handleFree(['p6','p17']);"
 value="ground? p" />
```

```
<div id="ansp17"><div></div></div>
```

```

```

```

```

```
<input type="submit" id="p18" class="subbut"
 onclick="makeRequest('p18');"
 value="ground?(1::POLY INT)" />
```

```
<div id="ansp18"><div></div></div>
```

```

```

```

```

The complete list of variables actually used in a particular polynomial is returned by [variables](dbopvariables.xhtml). For constant

polynomials, this list is empty.

```

 <input type="submit" id="p19" class="subbut"
 onclick="handleFree(['p6','p19']);"
 value="variables p" />
 <div id="ansp19"><div></div></div>

```

The [degree](dbopdegree.xhtml) operation returns the degree of a polynomial in a specific variable.

```

 <input type="submit" id="p20" class="subbut"
 onclick="handleFree(['p6','p20']);"
 value="degree(p,x)" />
 <div id="ansp20"><div></div></div>

 <input type="submit" id="p21" class="subbut"
 onclick="handleFree(['p6','p21']);"
 value="degree(p,y)" />
 <div id="ansp21"><div></div></div>

 <input type="submit" id="p22" class="subbut"
 onclick="handleFree(['p6','p22']);"
 value="degree(p,z)" />
 <div id="ansp22"><div></div></div>

```

If you give a list of variables for the second argument, a list of the degrees in those variables is returned.

```

 <input type="submit" id="p23" class="subbut"
 onclick="handleFree(['p6','p23']);"
 value="degree(p,[x,y,z])" />
 <div id="ansp23"><div></div></div>

```

The minimum degree of a variable in a polynomial is computed using [minimumDegree](dbopminimumdegree.xhtml).

```

 <input type="submit" id="p24" class="subbut"
```

```

 onclick="handleFree(['p6','p24']);"
 value="minimumDegree(p,z)" />
 <div id="ansp24"><div></div></div>

```

The total degree of a polynomial is returned by  
[totalDegree](dbopttotaldegree.xhtml).

```

 <input type="submit" id="p25" class="subbut"
 onclick="handleFree(['p6','p25']);"
 value="totalDegree p" />
 <div id="ansp25"><div></div></div>

```

It is often convenient to think of a polynomial as a leading monomial plus the remaining terms, using the operation

[leadingMonomial](dbopleadingmonomial.xhtml)

```

 <input type="submit" id="p26" class="subbut"
 onclick="handleFree(['p6','p26']);"
 value="leadingMonomial p" />
 <div id="ansp26"><div></div></div>

```

The [reductum](dbopreductum.xhtml) operation returns a polynomial consisting of the sum of the monomials after the first.

```

 <input type="submit" id="p27" class="subbut"
 onclick="handleFree(['p6','p27']);"
 value="reductum p" />
 <div id="ansp27"><div></div></div>

```

These have the obvious relationship that the original polynomial is equal to the leading monomial plus the reductum.

```

 <input type="submit" id="p28" class="subbut"
 onclick="handleFree(['p6','p28']);"
 value="p-leadingMonomial p - reductum p" />
 <div id="ansp28"><div></div></div>

```

The value returned by `<a href="dbopleadingmonomial.xhtml">leadingMonomial</a>` includes the coefficient of that term. This is extracted by using `<a href="dbopleadingcoefficient.xhtml">leadingCoefficient</a>` on the original polynomial.

```

 <input type="submit" id="p29" class="subbut"
 onclick="handleFree(['p6','p29']);"
 value="leadingCoefficient p" />
 <div id="ansp29"><div></div></div>

```

The operation `<a href="dbopeval.xhtml">eval</a>` is used to substitute a value for a variable in a polynomial.

```

 <input type="submit" id="p30" class="subbut"
 onclick="handleFree(['p6','p30']);"
 value="p" />
 <div id="ansp30"><div></div></div>

```

This value may be another variable, a constant or a polynomial.

```

 <input type="submit" id="p31" class="subbut"
 onclick="handleFree(['p6','p31']);"
 value="eval(p,x,w)" />
 <div id="ansp31"><div></div></div>

 <input type="submit" id="p32" class="subbut"
 onclick="handleFree(['p6','p32']);"
 value="eval(p,x,1)" />
 <div id="ansp32"><div></div></div>

```

Actually, all the things being substituted are just polynomials, some more trivial than others.

```

 <input type="submit" id="p33" class="subbut"
 onclick="handleFree(['p6','p33']);"
 value="eval(p,x,y^2-1)" />
 <div id="ansp33"><div></div></div>

```

</ul>

Derivatives are computed using the [D](dbopd.xhtml) operation.

<ul>

<li>

<div id="ansp34"><div></div></div>

</li>

</ul>

The first argument is the polynomial and the second is the variable.

<ul>

<li>

<div id="ansp35"><div></div></div>

</li>

</ul>

Even if the polynomial has only one variable, you must specify it.

<ul>

<li>

<div id="ansp36"><div></div></div>

</li>

</ul>

Integration of polynomials is similar and the

[integrate](dbopintegrate.xhtml) operation is used.

Integration requires that the coefficients support division.

Consequently, Axiom converts polynomials over the integers to polynomials over the rational numbers before integrating them.

<ul>

<li>

<div id="ansp37"><div></div></div>

</li>

</ul>

It is not possible, in general, to divide two polynomials. In our example using polynomials over the integers, the operation

[monicDivide](dbopmonicdivide.xhtml) divides a polynomial by a monic polynomial (that is, a polynomial with leading coefficient equal to

1). The result is a record of the quotient and remainder of the division. You must specify the variable in which to express the polynomial.

```

 <input type="submit" id="p38" class="subbut"
 onclick="handleFree(['p6','p38']);"
 value="qr:=monicDivide(p,x+1,x)" />
 <div id="ansp38"><div></div></div>

```

The selectors of the components of the record are quotient and remainder. Issue this to extract the remainder:

```

 <input type="submit" id="p39" class="subbut"
 onclick="handleFree(['p6','p38','p39']);"
 value="qr.remainder" />
 <div id="ansp39"><div></div></div>

```

Now that we can extract the components, we can demonstrate the relationship among them and the arguments to our original expression

```
<pre>
 qr:=monicDivide(p,x+1,x)
</pre>

 <input type="submit" id="p40" class="subbut"
 onclick="handleFree(['p6','p38','p40']);"
 value="p-((x+1)*qr.quotient+qr.remainder)" />
 <div id="ansp40"><div></div></div>

```

If the `<a href="dbopdivide.xhtml"></a>` operator is used with polynomials, a fraction object is created. In this example, the result is an object of type

`<a href="dbfractionpolynomialinteger.xhtml">Fraction Polynomial Integer</a>`.

```

 <input type="submit" id="p41" class="subbut"
 onclick="handleFree(['p6','p7','p41']);"
 value="p/q" />
 <div id="ansp41"><div></div></div>

```

If you use rational numbers as polynomial coefficients, the resulting

object is of type

[Polynomial Fraction Integer](dbpolynomialfractioninteger.xhtml)

```

 <input type="submit" id="p42" class="subbut"
 onclick="makeRequest('p42');"
 value="pfi:=(2/3)*x^2-y+4/5" />
 <div id="ansp42"><div></div></div>

```

This can be converted to a fraction of polynomials and back again, if required.

```

 <input type="submit" id="p43" class="subbut"
 onclick="handleFree(['p42','p43']);"
 value="fpi:=pfi::FRAC POLY INT" />
 <div id="ansp43"><div></div></div>

 <input type="submit" id="p44" class="subbut"
 onclick="handleFree(['p42','p43','p44']);"
 value="fpi::POLY FRAC INT" />
 <div id="ansp44"><div></div></div>

```

To convert the coefficients to floating point, map the

[numeric](dbopnumeric.xhtml) operation on the coefficients of the polynomial.

```

 <input type="submit" id="p45" class="subbut"
 onclick="handleFree(['p42','p45']);"
 value="map(numeric,pfi)" />
 <div id="ansp45"><div></div></div>

```

For more information on related topics, see

[UnivariatePolynomial](axbook/section-9.83.xhtml),

[MultivariatePolynomial](axbook/section-9.54.xhtml), and

[DistributedMultivariatePolynomial](axbook/section-9.16.xhtml).

You can also issue the system command

```

 <input type="submit" id="p46" class="subbut"
 onclick="showcall('p46');" />
```

```
value=")show Polynomial"/>
<div id="ansp46"><div></div></div>

to display the full list of operations defined by
Polynomial.
<page foot>
```

## 1.9.535 polyspecifictypes2.xhtml

```

<polyspecifictypes2.xhtml>≡
 <standard head>
 <script type="text/javascript">
 <handlefreevars>
 <axiom talker>
 </script>
 </head>
 <body onload="resetvars();">
 <page head>
 <div align="center">UnivariatePolynomial</div>
 <hr/>
 The domain constructor
 UnivariatePolynomial
 (abbreviated UP)
 creates domains of univariate polynomials in a specified variable.
 For example, the domain UP(a1,POLY FRAC INT) provides polynomials in
 the single variable a1 whose coefficients are general polynomials with
 rational number coefficients.
 <hr/>
 Restriction:

 Axiom does not allow you to create types where
 UnivariatePolynomial
 is contained in the coefficient type of
 Polynomial.
 Therefore, UP(x,POLY INT) is legal but POLY UP(x,INT) is not.
 <hr/>
 UP(x,INT) is the domain of polynomials in the single variable x with
 integer coefficients.

 <input type="submit" id="p1" class="subbut"
 onclick="makeRequest('p1');"
 value="(p,q):UP(x,INT)" />
 <div id="ansp1"><div></div></div>

 <input type="submit" id="p2" class="subbut"
 onclick="makeRequest('p2');"
 value="p:=(3*x-1)^2*(2*x+8)" />
 <div id="ansp2"><div></div></div>

 <input type="submit" id="p3" class="subbut"
 onclick="makeRequest('p3');"

```

```

 value="q:=(1-6*x+9*x^2)^2" />
 <div id="ansp3"><div></div></div>

```

The usual arithmetic operations are available for univariate polynomials.

```

 <input type="submit" id="p4" class="subbut"
 onclick="handleFree(['p1','p2','p3','p4']);"
 value="p^2+p*q" />
 <div id="ansp4"><div></div></div>

```

The operation

[leadingCoefficient](dbopleadingcoefficient.xhtml) extracts the coefficient of the term of highest degree.

```

 <input type="submit" id="p5" class="subbut"
 onclick="handleFree(['p1','p2','p5']);"
 value="leadingCoefficient p" />
 <div id="ansp5"><div></div></div>

```

The operation [degree](dbopdegree.xhtml) returns the degree of the polynomial. Since the polynomial has only one variable, the variable is not supplied to operations like [degree](dbopdegree.xhtml).

```

 <input type="submit" id="p6" class="subbut"
 onclick="handleFree(['p1','p2','p6']);"
 value="degree p" />
 <div id="ansp6"><div></div></div>

```

The reductum of the polynomial, the polynomial obtained by subtracting the term of highest order, is returned by

[reductum](dbopreductum.xhtml).

```

 <input type="submit" id="p7" class="subbut"
 onclick="handleFree(['p1','p2','p7']);"
 value="reductum p" />
 <div id="ansp7"><div></div></div>

```

The operation [gcd](dbopgcd.xhtml) computes the greatest common divisor of two polynomials.

```

 <input type="submit" id="p8" class="subbut"
 onclick="handleFree(['p1','p2','p3','p8']);"
 value="gcd(p,q)" />
 <div id="ansp8"><div></div></div>

```

The operation [lcm](dboplcm.xhtml) computes the least common multiple.

```

 <input type="submit" id="p9" class="subbut"
 onclick="handleFree(['p1','p2','p3','p9']);"
 value="lcm(p,q)" />
 <div id="ansp9"><div></div></div>

```

The operation [resultant](dbopresultant.xhtml) computes the resultant of two univariate polynomials. In the case of  $p$  and  $q$ , the resultant is 0 because they share a common root.

```

 <input type="submit" id="p10" class="subbut"
 onclick="handleFree(['p1','p2','p3','p10']);"
 value="resultant(p,q)" />
 <div id="ansp10"><div></div></div>

```

To compute the derivative of a univariate polynomial with respect to its variable, use [D](dbopd.xhtml).

```

 <input type="submit" id="p11" class="subbut"
 onclick="handleFree(['p1','p2','p11']);"
 value="D p" />
 <div id="ansp11"><div></div></div>

```

Univariate polynomials can also be used as if they were functions.

To evaluate a univariate polynomial at some point, apply the polynomial to the point.

```

```

```

<div></div></div>

```

The same syntax is used for composing two univariate polynomials, i.e. substituting one polynomial for the variable in another. This substitutes  $q$  for the variable in  $p$ .

```

<div></div></div>

```

This substitutes  $p$  for the variable in  $q$ .

```

<div></div></div>

```

To obtain a list of coefficients of the polynomial, use

[coefficients](dbopcoefficients.xhtml).

```

<div></div></div>

```

From this you can use [gcd](dbopgcd.xhtml) and

[reduce](dbopreduce.xhtml) to compute the contents of the polynomial.

```

<div></div></div>

```

```

```

Alternatively (and more easily), you can just call

```
content
```

```

```

```

```

```
 <input type="submit" id="p17" class="subbut"
 onclick="handleFree(['p1','p2','p17']);"
 value="content p" />
```

```
 <div id="ansp17"><div></div></div>
```

```

```

```

```

Note that the operation `<a href="dbopcoefficients.xhtml">coefficients</a>` omits the zero coefficients from the list. Sometimes it is useful to convert a univariate polynomial to a vector whose  $i$ -th position contains the degree  $i-1$  coefficient of the polynomial.

```

```

```

```

```
 <input type="submit" id="p18" class="subbut"
 onclick="makeRequest('p18');"
 value="ux:=(x^4+2*x+3)::UP(x,INT)" />
```

```
 <div id="ansp18"><div></div></div>
```

```

```

```

```

To get a complete vector of coefficients, use the operation

`<a href="dbopvectorise.xhtml">vectorise</a>`, which takes a univariate polynomial and an integer denoting the length of the desired vector.

```

```

```

```

```
 <input type="submit" id="p19" class="subbut"
 onclick="handleFree(['p18','p19']);"
 value="vectorise(ux,5)" />
```

```
 <div id="ansp19"><div></div></div>
```

```

```

```

```

It is common to want to do something to every term of a polynomial, creating a new polynomial in the process. This is a function for iterating across the terms of a polynomial, squaring each term.

```

```

```

```

```
 <input type="submit" id="p20" class="subbut"
 onclick="makeRequest('p20');"
 value="squareTerms(m)==reduce(+,[t^2 for t in monomials m])" />
```

```
 <div id="ansp20"><div></div></div>
```

```

```

```

```

Recall what `p` looked like.

```

 <input type="submit" id="p21" class="subbut"
 onclick="handleFree(['p1','p2','p21']);"
 value="p" />
 <div id="ansp21"><div></div></div>

```

We can demonstrate squareTerms on p.

```

 <input type="submit" id="p22" class="subbut"
 onclick="handleFree(['p1','p2','p20','p22']);"
 value="squareTerms p" />
 <div id="ansp22"><div></div></div>

```

When the coefficients of the univariate polynomial belong to a field, (for example, when the coefficients are rational numbers, as opposed to integers. The important property of a field is that non-zero elements can be divided and produce another element. The quotient of the integers 2 and 3 is not another integer.) It is possible to compute quotients and remainders.

```

 <input type="submit" id="p23" class="subbut"
 onclick="makeRequest('p23');"
 value="(r,s):UP(a1,FRAC INT)" />
 <div id="ansp23"><div></div></div>

 <input type="submit" id="p24" class="subbut"
 onclick="handleFree(['p23','p24']);"
 value="r:=a1^2-2/3" />
 <div id="ansp24"><div></div></div>

 <input type="submit" id="p25" class="subbut"
 onclick="handleFree(['p23','p25']);"
 value="s:=a1+4" />
 <div id="ansp25"><div></div></div>

```

When the coefficients are rational numbers or rational expressions, the operation `<a href="dbopquo.xhtml">quo</a>` computes the quotient of two polynomials.

```

```

```

 <input type="submit" id="p26" class="subbut"
 onclick="handleFree(['p23','p24','p25','p26']);"
 value="r quo s" />
 <div id="ansp26"><div></div></div>

```

The operation [rem](dboprem.xhtml) computes the remainder.

```

 <input type="submit" id="p27" class="subbut"
 onclick="handleFree(['p23','p24','p25','p27']);"
 value="r rem s" />
 <div id="ansp27"><div></div></div>

```

The operation [divide](dbopdivide.xhtml) can be used to return a record of both components.

```

 <input type="submit" id="p28" class="subbut"
 onclick="handleFree(['p23','p24','p25','p28']);"
 value="d:=divide(r,s)" />
 <div id="ansp28"><div></div></div>

```

Now we check the arithmetic.

```

 <input type="submit" id="p29" class="subbut"
 onclick="handleFree(['p23','p24','p25','p28','p29']);"
 value="r-(d.quotient*s+d.remainder)" />
 <div id="ansp29"><div></div></div>

```

It is also possible to integrate univariate polynomials when the coefficients belong to a field.

```

 <input type="submit" id="p30" class="subbut"
 onclick="handleFree(['p23','p24','p30']);"
 value="integrate r" />
 <div id="ansp30"><div></div></div>

 <input type="submit" id="p31" class="subbut"

```

```

 onclick="handleFree(['p23','p25','p31']);"
 value="integrate s" />
 <div id="ansp31"><div></div></div>

```

One application of univariate polynomials is to see expressions in terms of a specific variable. We start with a polynomial in  $a_1$  whose coefficients are quotients of polynomials in  $b_1$  and  $b_2$ .

```

 <input type="submit" id="p32" class="subbut"
 onclick="makeRequest('p32');"
 value="t:UP(a1,FRAC POLY INT)" />
 <div id="ansp32"><div></div></div>

```

Since in this case we are not talking about using multivariate polynomials in only two variables, we use [Polynomial](db.xhtml?Polynomial). We also use [Fraction](db.xhtml?Fraction) because we want fractions.

```

 <input type="submit" id="p33" class="subbut"
 onclick="handleFree(['p32','p33']);"
 value="t:=a1^2-a1/b2+(b1^2-b1)/(b2+3)" />
 <div id="ansp33"><div></div></div>

```

We push all the variables into a single quotient of polynomials.

```

 <input type="submit" id="p34" class="subbut"
 onclick="handleFree(['p32','p33','p34']);"
 value="u:FRAC POLY INT:=t" />
 <div id="ansp34"><div></div></div>

```

Alternatively, we can view this as a polynomial in the variable. This is a mode-directed conversion: You indicate as much of the structure as you care about and let Axiom decide on the full type and how to do the transformation.

```

 <input type="submit" id="p35" class="subbut"
 onclick="handleFree(['p32','p33','p34','p35']);"
 value="u:UP(b1,?)" />
 <div id="ansp35"><div></div></div>

```

```

See Polynomial Factorization for a
discussion of the factorization facilities in Axiom for univariate
polynomials. For more information on related topics, see
Polynomials,
Conversion,
Polynomial,
MultivariatePolynomial, and
DistributedMultivariatePolynomial.
Issue the system command

 <input type="submit" id="p36" class="subbut"
 onclick="showcall('p36');"
 value=")show UnivariatePolynomial"/>
 <div id="ansp36"><div></div></div>

to display the full list of operations defined by
UnivariatePolynomial.

```

### 1.9.536 polyspecifictypes3.xhtml

*(polyspecifictypes3.xhtml)*≡

```

<standard head>
 <script type="text/javascript">
 <handlefreevars>
 <axiom talker>
 </script>
</head>
<body onload="resetvars();">
 <page head>
 <div align="center">MultivariatePolynomial</div>
 <hr/>

```

The domain constructor

[MultivariatePolynomial](db.xhtml?MultivariatePolynomial) is similar to [Polynomial](db.xhtml?Polynomial) except that it specifies the variables to be used.

[Polynomial](db.xhtml?Polynomial) are available for

[MultivariatePolynomial](db.xhtml?MultivariatePolynomial).

The abbreviation for

[MultivariatePolynomial](db.xhtml?MultivariatePolynomial) is

[MPOLY](db.xhtml?MultivariatePolynomial). The type expressions

```
<pre>
```

```
 MultivariatePolynomial([x,y],Integer)
```

```
</pre>
```

and

```
<pre>
```

```
 MPOLY([x,y],INT)
```

```
</pre>
```

refer to the domain of multivariate polynomials in the variables  $x$  and  $y$  where the coefficients are restricted to be integers. The first variable specified is the main variable and the display of the polynomial reflects this. This polynomial appears with terms in descending powers of the variable  $x$ .

```

```

```

```

```
 <input type="submit" id="p1" class="subbut"
```

```
 onclick="makeRequest('p1');"
```

```
 value="m:MPOLY([x,y],INT):=(x^2-x*y^3+3*y)^2" />
```

```
 <div id="ansp1"><div></div></div>
```

```

```

```

```

It is easy to see a different variable ordering by doing a conversion.

```

```

```

```

```
 <input type="submit" id="p2" class="subbut"
```

```

 onclick="handleFree(['p1','p2']);"
 value="m::MPOLY([y,x],INT)" />
 <div id="ansp2"><div></div></div>

```

You can use other, unspecified variables, by using

[Polynomial](db.xhtml?Polynomial) in the coefficient type of  
[MPOLY](db.xhtml?MultivariatePolynomial).

```

 <input type="submit" id="p3" class="subbut"
 onclick="makeRequest('p3');"
 value="p::MPOLY([x,y],POLY INT):=(a^2*x-b*y^2+1)^2" />
 <div id="ansp3"><div></div></div>

```

Conversions can be used to re-express such polynomials in terms of the other variables. For example, you can first push all the variables into a polynomial with integer coefficients.

```

 <input type="submit" id="p4" class="subbut"
 onclick="handleFree(['p3','p4']);"
 value="u:=p::POLY INT" />
 <div id="ansp4"><div></div></div>

```

Now pull out the variables of interest.

```

 <input type="submit" id="p5" class="subbut"
 onclick="handleFree(['p3','p4','p5']);"
 value="u::MPOLY([a,b],POLY INT)" />
 <div id="ansp5"><div></div></div>

```

<hr/>

**Restriction:** Axiom does not allow you to create types where

[MultivariatePolynomial](db.xhtml?MultivariatePolynomial) is contained in the coefficient type of

[Polynomial](db.xhtml?Polynomial). Therefore,

```

<pre>
 MPOLY([x,y],POLY INT)

```

</pre>

is legal but this is not:

```

<pre>

```

```
POLY MPOLY([x,y],INT)n
```

```
</pre>
```

```
<hr/>
```

Multivariate polynomials may be combined with univariate polynomials to create types with special structures.

```

```

```

```

```
<input type="submit" id="p6" class="subbut"
```

```
 onclick="makeRequest('p6');"
```

```
 value="q:UP(x,FRAC MPOLY([y,z],INT)):(x^2-x*(z+1)/y+2)^2" />
```

```
<div id="ansp6"><div></div></div>
```

```

```

```

```

This is a polynomial in  $x$  whose coefficients are quotients of polynomials in  $y$  and  $z$ . Use conversions for the structural rearrangements.  $z$  does not appear in a denominator and so it can be made the main variable.

```

```

```

```

```
<input type="submit" id="p7" class="subbut"
```

```
 onclick="handleFree(['p6','p7']);"
```

```
 value="q:UP(z,FRAC MPOLY([x,y],INT))" />
```

```
<div id="ansp7"><div></div></div>
```

```

```

```

```

Or you can make a multivariate polynomial in  $x$  and  $z$  whose coefficients are fractions in polynomials in  $y$

```

```

```

```

```
<input type="submit" id="p8" class="subbut"
```

```
 onclick="handleFree(['p6','p8']);"
```

```
 value="q:MPOLY([x,z],FRAC UP(y,INT))" />
```

```
<div id="ansp8"><div></div></div>
```

```

```

```

```

A conversion like

```
<pre>
```

```
 q:MPOLY([x,y],FRAC UP(z,INT))
```

```
</pre>
```

is not possible in this example because  $y$  appears in the denominator of a fraction. As you can see, Axiom provides extraordinary flexibility in the manipulation and display of expressions via its conversion facility.

### 1.9.537 polyspecifictypes4.xhtml

```

<polyspecifictypes4.xhtml>≡
 <standard head>
 <script type="text/javascript">
 <handlefreevars>
 <axiom talker>
 </script>
 </head>
 <body onload="resetvars();">
 <page head>
 <div align="center">DistributedMultivariatePolynomial</div>
 <hr/>

DistributedMultivariatePolynomial and

HomogeneousDistributedMultivariatePolynomial, abbreviated
 DMP and
 HDMP
respectively, are very similar to
 MultivariatePolynomial
except that they are represented and displayed in a non-recursive manner.

 <input type="submit" id="p1" class="subbut"
 onclick="makeRequest('p1');"
 value="(d1,d2,d3):DMP([z,y,x],FRAC INT)" />
 <div id="ansp1"><div></div></div>

 The construction
 DMP orders its
monomials lexicographically while
 HDMP
orders them by total order refined by reverse lexicographic order.

 <input type="submit" id="p2" class="subbut"
 onclick="handleFree(['p1','p2']);"
 value="d1:=-4*z+4*y^2*x+16*x^2+1" />
 <div id="ansp2"><div></div></div>

 <input type="submit" id="p3" class="subbut"
 onclick="handleFree(['p1','p3']);"
 value="d2:=2*z*y^2+4*x+1" />

```

```

 <div id="ansp3"><div></div></div>

 <input type="submit" id="p4" class="subbut"
 onclick="handleFree(['p1','p4']);"
 value="d3:=2*z*x^2-2*y^2-x" />
 <div id="ansp4"><div></div></div>

```

These constructors are mostly used in Groebner basis calculations.

```

 <input type="submit" id="p5" class="subbut"
 onclick="handleFree(['p1','p2','p3','p4','p5']);"
 value="groebner [d1,d2,d3]" />
 <div id="ansp5"><div></div></div>

 <input type="submit" id="p6" class="subbut"
 onclick="makeRequest('p6');"
 value="(n1,n2,n3):HDMP([z,y,x],FRAC INT)" />
 <div id="ansp6"><div></div></div>

 <input type="submit" id="p7" class="subbut"
 onclick="handleFree(['p1','p2','p3','p4','p6','p7']);"
 value="(n1,n2,n3):=(d1,d2,d3)" />
 <div id="ansp7"><div></div></div>

```

Note that we get a different Groebner basis when we use the

[HomogeneousDistributedMultivariatePolynomial](db.xhtml?HomogeneousDistributedMultivariatePolynomial) HDMP [polynomials](#), as expected.

```

 <input type="submit" id="p8" class="subbut"
 onclick="handleFree(['p1','p2','p3','p4','p6','p7','p8']);"
 value="groebner [n1,n2,n3]" />
 <div id="ansp8"><div></div></div>

```

[GeneralDistributedMultivariatePolynomial](db.xhtml?GeneralDistributedMultivariatePolynomial)

GeneralDistributedMultivariatePolynomial is somewhat more flexible in the sense that as well as accepting a list of variables to specify the variable ordering, it also takes a predicate on exponent vectors to specify the term ordering. With this polynomial type the user can experiment with

the effect of using completely arbitrary term orderings. This flexibility is mostly important for algorithms such as Groebner basis calculations which can be very sensitive to term orderings.

## 1.9.538 polysubstitutions.xhtml

```

<polysubstitutions.xhtml>≡
 <standard head>
 <script type="text/javascript">
 <handlefreevars>
 <axiom talker>
 </script>
 </head>
 <body onload="resetvars();">
 <page head>
 <div align="center">Polynomial Evaluation and Substitution</div>
 <hr/>

```

The function `<a href="dbopeval.xhtml">eval</a>` is used to substitute values into polynomials. Here's an example of how to use it:

```

 <input type="submit" id="p1" class="subbut"
 onclick="makeRequest('p1');"
 value="p:=x^2+y^2" />
 <div id="ansp1"><div></div></div>

 <input type="submit" id="p2" class="subbut"
 onclick="handleFree(['p1','p2']);"
 value="eval(p,x=5)" />
 <div id="ansp2"><div></div></div>

```

This example would give you the value of the polynomial  $p$  at 5. You can also substitute into polynomials with several variables. First, specify the polynomial, then give a list of the bindings of the form

```

<pre>
 variable = value
</pre>

```

For examples:

```

 <input type="submit" id="p3" class="subbut"
 onclick="handleFree(['p1','p3']);"
 value="eval(p,[x=a+b,y=c+d])" />
 <div id="ansp3"><div></div></div>

```

Here  $x$  was replaced by  $a+b$ , and  $y$  was replaced by  $c+d$ .

```

```

```

 <input type="submit" id="p4" class="subbut"
 onclick="makeRequest('p4');"
 value="q:=x^3+5*x-y^4" />
 <div id="ansp4"><div></div></div>

 <input type="submit" id="p5" class="subbut"
 onclick="handleFree(['p4','p5']);"
 value="eval(q,[x=y,y=x])" />
 <div id="ansp5"><div></div></div>

```

Substitution is done "in parallel". That is, Axiom takes  $q(x,y)$  and returns  $q(y,x)$ .

You can also substitute numerical values for some or all of the variables.

```

 <input type="submit" id="p6" class="subbut"
 onclick="handleFree(['p1','p6']);"
 value="px:=eval(p,y=sin(2.0))" />
 <div id="ansp6"><div></div></div>

 <input type="submit" id="p7" class="subbut"
 onclick="handleFree(['p1','p6','p7']);"
 value="eval(px,x=cos(2.0))" />
 <div id="ansp7"><div></div></div>

```

*<page foot>*

 <page head>
 The November 2007 release of Axiom contains

 New MathML output mode. This mode allows Axiom to output expressions
 using standard MathML format. This complements the existing ability
 to output Fortran, IBM script, Latex, OpenMath, and algebra formats.

 Ninety-five domains have been documented for the)help command.
 Type)help to see the list.

 New regression tests were added to improve the release testing.

 Hyperdoc can now be restarted. Type)hd

 Testing has begun against Spiegel's Mathematical Handbook from the
 Schaum's Outline Series. These tests include Axiom's solutions and
 have uncovered mistakes in the published text.

 Bug fixes

 Bug100 integrate((z^a+1)^b,z) no longer loops infinitely.

 Bug101 laplace(log(z),z,w) returns "failed" instead of crashing.

 Bug103 solve(z=z,z) returns the correct answer
