++ s18def(fnu,z,n,scale,ifail)
++ returns a sequence of values for the modified Bessel functions
++ I      (z) for complex z, non-negative (nu) and
++      (nu)+n
++ n=0,1,...,N-1, with an option for exponential scaling.
++ See \downlink{Manual Page}{manpageXXs18def}.
s19aaf : (DoubleFloat,Integer) -> Result
++ s19aaf(x,ifail)
++ returns a value for the Kelvin function ber(x) via the
++ routine name.
++ See \downlink{Manual Page}{manpageXXs19aaf}.
s19abf : (DoubleFloat,Integer) -> Result
++ s19abf(x,ifail)
++ returns a value for the Kelvin function bei(x) via the
++ routine name.
++ See \downlink{Manual Page}{manpageXXs19abf}.
s19acf : (DoubleFloat,Integer) -> Result
++ s19acf(x,ifail)
++ returns a value for the Kelvin function ker(x), via the
++ routine name.
++ See \downlink{Manual Page}{manpageXXs19acf}.
s19adf : (DoubleFloat,Integer) -> Result
++ s19adf(x,ifail)
++ returns a value for the Kelvin function kei(x) via the
++ routine name.
++ See \downlink{Manual Page}{manpageXXs19adf}.
s20acf : (DoubleFloat,Integer) -> Result
++ s20acf(x,ifail)
++ returns a value for the Fresnel Integral S(x), via the
++ routine name.
++ See \downlink{Manual Page}{manpageXXs20acf}.
s20adf : (DoubleFloat,Integer) -> Result
++ s20adf(x,ifail)
++ returns a value for the Fresnel Integral C(x), via the
++ routine name.
++ See \downlink{Manual Page}{manpageXXs20adf}.
s21baf : (DoubleFloat,DoubleFloat,Integer) -> Result

```

```

++ s21baf(x,y,ifail)
++ returns a value of an elementary integral, which occurs as
++ a degenerate case of an elliptic integral of the first kind, via
++ the routine name.
++ See \downlink{Manual Page}{manpageXXs21baf}.
s21bbf : (DoubleFloat,DoubleFloat,DoubleFloat,Integer) -> Result
++ s21bbf(x,y,z,ifail)
++ returns a value of the symmetrised elliptic integral of
++ the first kind, via the routine name.
++ See \downlink{Manual Page}{manpageXXs21bbf}.
s21bcf : (DoubleFloat,DoubleFloat,DoubleFloat,Integer) -> Result
++ s21bcf(x,y,z,ifail)
++ returns a value of the symmetrised elliptic integral of
++ the second kind, via the routine name.
++ See \downlink{Manual Page}{manpageXXs21bcf}.
s21bdf : (DoubleFloat,DoubleFloat,DoubleFloat,DoubleFloat,_
Integer) -> Result
++ s21bdf(x,y,z,r,ifail)
++ returns a value of the symmetrised elliptic integral of
++ the third kind, via the routine name.
++ See \downlink{Manual Page}{manpageXXs21bdf}.

### 15.27.1 NumberFieldIntegralBasis (NFINTBAS)

#### Exports:

discriminant integralBasis localIntegralBasis

*<package NFINTBAS NumberFieldIntegralBasis>=*

)abbrev package NFINTBAS NumberFieldIntegralBasis

++ Author: Victor Miller, Clifton Williamson

++ Date Created: 9 April 1990

++ Date Last Updated: 20 September 1994

++ Basic Operations: discriminant, integralBasis

++ Related Domains: IntegralBasisTools, TriangularMatrixOperations

++ Also See: FunctionFieldIntegralBasis, WildFunctionFieldIntegralBasis

++ AMS Classifications:

++ Keywords: number field, integral basis, discriminant

++ Examples:

++ References:

++ Description:

++ In this package F is a framed algebra over the integers (typically  
 ++ \spad{F = Z[a]} for some algebraic integer a). The package provides  
 ++ functions to compute the integral closure of Z in the quotient  
 ++ quotient field of F.

NumberFieldIntegralBasis(UP,F): Exports == Implementation where

UP : UnivariatePolynomialCategory Integer

F : FramedAlgebra(Integer,UP)

FR ==> Factored Integer

I ==> Integer

Mat ==> Matrix I

NNI ==> NonNegativeInteger

Ans ==> Record(basis: Mat, basisDen: I, basisInv:Mat,discr: I)

```

Exports ==> with
discriminant: () -> Integer
  ++ \spad{discriminant()} returns the discriminant of the integral
  ++ closure of Z in the quotient field of the framed algebra F.
integralBasis : () -> Record(basis: Mat, basisDen: I, basisInv:Mat)
  ++ \spad{integralBasis()} returns a record
  ++ \spad{[basis,basisDen,basisInv]}
  ++ containing information regarding the integral closure of Z in the
  ++ quotient field of F, where F is a framed algebra with Z-module
  ++ basis \spad{w1,w2,...,wn}.
  ++ If \spad{basis} is the matrix \spad{(aij, i = 1..n, j = 1..n)}, then
  ++ the \spad{i}th element of the integral basis is
  ++ \spad{vi = (1/basisDen) * sum(aij * wj, j = 1..n)}, i.e. the
  ++ \spad{i}th row of \spad{basis} contains the coordinates of the
  ++ \spad{i}th basis vector. Similarly, the \spad{i}th row of the
  ++ matrix \spad{basisInv} contains the coordinates of \spad{wi} with
  ++ respect to the basis \spad{v1,...,vn}: if \spad{basisInv} is the
  ++ matrix \spad{(bij, i = 1..n, j = 1..n)}, then
  ++ \spad{wi = sum(bij * vj, j = 1..n)}.
localIntegralBasis : I -> Record(basis: Mat, basisDen: I, basisInv:Mat)
  ++ \spad{integralBasis(p)} returns a record
  ++ \spad{[basis,basisDen,basisInv]} containing information regarding
  ++ the local integral closure of Z at the prime \spad{p} in the quotient
  ++ field of F, where F is a framed algebra with Z-module basis
  ++ \spad{w1,w2,...,wn}.
  ++ If \spad{basis} is the matrix \spad{(aij, i = 1..n, j = 1..n)}, then
  ++ the \spad{i}th element of the integral basis is
  ++ \spad{vi = (1/basisDen) * sum(aij * wj, j = 1..n)}, i.e. the
  ++ \spad{i}th row of \spad{basis} contains the coordinates of the
  ++ \spad{i}th basis vector. Similarly, the \spad{i}th row of the
  ++ matrix \spad{basisInv} contains the coordinates of \spad{wi} with
  ++ respect to the basis \spad{v1,...,vn}: if \spad{basisInv} is the
  ++ matrix \spad{(bij, i = 1..n, j = 1..n)}, then
  ++ \spad{wi = sum(bij * vj, j = 1..n)}.

#### Exports:

rk4 rk4a rk4f rk4qc rk4qc

```

(package NUMODE NumericalOrdinaryDifferentialEquations)≡
)abbrev package NUMODE NumericalOrdinaryDifferentialEquations
++ Author: Yuriy Baransky
++ Date Created: October 90
++ Date Last Updated: October 90
++ Basic Operations:
++ Related Constructors:
++ Also See:
++ AMS Classifications:
++ Keywords:
++ References:
++ Description:
++ This package is a suite of functions for the numerical integration of an
++ ordinary differential equation of n variables:\br
++ \tab{5}dy/dx = f(y,x)\tab{5}y is an n-vector\br
++ All the routines are based on a 4-th order Runge-Kutta kernel.
++ These routines generally have as arguments:\br
++ n, the number of dependent variables;\br
++ x1, the initial point;\br
++ h, the step size;\br
++ y, a vector of initial conditions of length n\br
++ which upon exit contains the solution at \spad{x1 + h};\br
++
++ \spad{derivs}, a function which computes the right hand side of the
++ ordinary differential equation: \spad{derivs(dydx,y,x)} computes
++ \spad{dydx}, a vector which contains the derivative information.
  
```

```

++
++ In order of increasing complexity:\br
++ \tab{5}\spad{rk4(y,n,x1,h,derivs)} advances the solution vector to\br
++ \tab{5}\spad{x1 + h} and return the values in y.\br
++
++ \tab{5}\spad{rk4(y,n,x1,h,derivs,t1,t2,t3,t4)} is the same as\br
++ \tab{5}\spad{rk4(y,n,x1,h,derivs)} except that you must provide 4 scratch\br
++ \tab{5}arrays t1-t4 of size n.\br
++
++ \tab{5}Starting with y at x1, \spad{rk4f(y,n,x1,x2,ns,derivs)}\br
++ \tab{5}uses \spad{ns} fixed steps of a 4-th order Runge-Kutta\br
++ \tab{5}integrator to advance the solution vector to x2 and return\br
++ \tab{5}the values in y. Argument x2, is the final point, and\br
++ \tab{5}\spad{ns}, the number of steps to take.
++
++ \spad{rk4qc(y,n,x1,step,eps,yscal,derivs)} takes a 5-th order
++ Runge-Kutta step with monitoring of local truncation to ensure
++ accuracy and adjust stepsize.
++ The function takes two half steps and one full step and scales
++ the difference in solutions at the final point. If the error is
++ within \spad{eps}, the step is taken and the result is returned.
++ If the error is not within \spad{eps}, the stepsize is decreased
++ and the procedure is tried again until the desired accuracy is
++ reached. Upon input, an trial step size must be given and upon
++ return, an estimate of the next step size to use is returned as
++ well as the step size which produced the desired accuracy.
++ The scaled error is computed as\br
++ \tab{5}\spad{error = MAX(ABS((y2steps(i) - y1step(i))/yscal(i)))}\br
++ and this is compared against \spad{eps}. If this is greater
++ than \spad{eps}, the step size is reduced accordingly to\br
++ \tab{5}\spad{hnew = 0.9 * hdid * (error/eps)**(-1/4)}\br
++ If the error criterion is satisfied, then we check if the
++ step size was too fine and return a more efficient one. If
++ \spad{error > \spad{eps} * (6.0E-04)} then the next step size should be\br
++ \tab{5}\spad{hnext = 0.9 * hdid * (error/\spad{eps})**(-1/5)}\br
++ Otherwise \spad{hnext = 4.0 * hdid} is returned.
++ A more detailed discussion of this and related topics can be
++ found in the book "Numerical Recipies" by W.Press, B.P. Flannery,
++ S.A. Teukolsky, W.T. Vetterling published by Cambridge University Press.
++
++ Argument \spad{step} is a record of 3 floating point
++ numbers \spad{(try , did , next)},
++ \spad{eps} is the required accuracy,
++ \spad{yscal} is the scaling vector for the difference in solutions.
++ On input, \spad{step.try} should be the guess at a step
++ size to achieve the accuracy.

```

```

++ On output, \spad{step.did} contains the step size which achieved the
++ accuracy and \spad{step.next} is the next step size to use.
++
++ \spad{rk4qc(y,n,x1,step,eps,yscal,derivs,t1,t2,t3,t4,t5,t6,t7)} is the
++ same as \spad{rk4qc(y,n,x1,step,eps,yscal,derivs)} except that the user
++ must provide the 7 scratch arrays \spad{t1-t7} of size n.
++
++ \spad{rk4a(y,n,x1,x2,eps,h,ns,derivs)}
++ is a driver program which uses \spad{rk4qc} to integrate n ordinary
++ differential equations starting at x1 to x2, keeping the local
++ truncation error to within \spad{eps} by changing the local step size.
++ The scaling vector is defined as\br
++ \tab{5}\spad{yscal(i) = abs(y(i)) + abs(h*dydx(i)) + tiny}\br
++ where \spad{y(i)} is the solution at location x, \spad{dydx} is the
++ ordinary differential equation's right hand side, h is the current
++ step size and \spad{tiny} is 10 times the
++ smallest positive number representable.
++
++ The user must supply an estimate for a trial step size and
++ the maximum number of calls to \spad{rk4qc} to use.
++ Argument x2 is the final point,
++ \spad{eps} is local truncation,
++ \spad{ns} is the maximum number of call to \spad{rk4qc} to use.

(package NUMQUAD NumericalQuadrature)≡
)abbrev package NUMQUAD NumericalQuadrature
++ Author: Yuriy A. Baransky
++ Date Created: October 90
++ Date Last Updated: October 90
++ Basic Operations:
++ Related Constructors:
++ Also See:
++ AMS Classifications:
++ Keywords:
++ References:
++ Description:
++ This suite of routines performs numerical quadrature using
++ algorithms derived from the basic trapezoidal rule. Because
++ the error term of this rule contains only even powers of the
++ step size (for open and closed versions), fast convergence
++ can be obtained if the integrand is sufficiently smooth.
++
++ Each routine returns a Record of type TrapAns, which contains
++ value Float: estimate of the integral
++ error Float: estimate of the error in the computation
++ totalpts Integer: total number of function evaluations
++ success Boolean: if the integral was computed within the user
++ specified error criterion
++ To produce this estimate, each routine generates an internal
++ sequence of sub-estimates, denoted by S(i), depending on the
++ routine, to which the various convergence criteria are applied.

```

```

++ The user must supply a relative accuracy, \spad{eps_r}, and an absolute
++ accuracy, \spad{eps_a}. Convergence is obtained when either\br
++ \tab{5}\spad{ABS(S(i) - S(i-1)) < eps_r * ABS(S(i-1))}\br
++ \tab{5}or \spad{ABS(S(i) - S(i-1)) < eps_a}
++ are true statements.
++
++ The routines come in three families and three flavors:
++ closed: romberg, simpson, trapezoidal
++ open: rombergo, simpsono, trapezoidal
++ adaptive closed: aromberg, asimpson, atrapezoidal
++
++ The S(i) for the trapezoidal family is the value of the
++ integral using an equally spaced abscissa trapezoidal rule for
++ that level of refinement.
++
++ The S(i) for the simpson family is the value of the integral
++ using an equally spaced abscissa simpson rule for that level of
++ refinement.
++
++ The S(i) for the romberg family is the estimate of the integral
++ using an equally spaced abscissa romberg method. For
++ the i-th level, this is an appropriate combination of all the
++ previous trapezoidal estimates so that the error term starts
++ with the 2*(i+1) power only.
++
++ The three families come in a closed version, where the formulas
++ include the endpoints, an open version where the formulas do not
++ include the endpoints and an adaptive version, where the user
++ is required to input the number of subintervals over which the
++ appropriate closed family integrator will apply with the usual
++ convergence parameters for each subinterval. This is useful
++ where a large number of points are needed only in a small fraction
++ of the entire domain.
++
++ Each routine takes as arguments:\br
++ f integrand\br
++ a starting point\br
++ b ending point\br
++ eps_r relative error\br
++ eps_a absolute error\br
++ nmin refinement level when to start checking for convergence (> 1)\br
++ nmax maximum level of refinement\br
++
++ The adaptive routines take as an additional parameter,
++ nint, the number of independent intervals to apply a closed
++ family integrator of the same name.

```

```

++
++ Notes:\br
++ Closed family level i uses \spad{1 + 2**i} points.\br
++ Open family level i uses \spad{1 + 3**i} points.\br

++ with the refinement levels for convergence checking vary from
++ \spad{nmin} to \spad{nmax}. The value returned
++ is a record containing the value of the integral, the estimate of
++ the error in the computation, the total number of function
++ evaluations, and either a boolean value which is true if
++ the integral was computed within the user specified error criterion.
++ See \spadtype{NumericalQuadrature} for details.
trapezoidal : (F -> F,F,F,F,F,I,I) -> TrapAns
++ trapezoidal(fn,a,b,epsrel,epsabs,nmin,nmax) uses the
++ trapezoidal method to numerically integrate function \spad{fn}
++ over the open interval from \spad{a} to \spad{b}, with
++ relative accuracy \spad{epsrel} and absolute accuracy \spad{epsabs},
++ with the refinement levels for convergence checking vary from
++ \spad{nmin} to \spad{nmax}. The value returned
++ is a record containing the value of the integral, the estimate of
++ the error in the computation, the total number of function
++ evaluations, and either a boolean value which is true if
++ the integral was computed within the user specified error criterion.
++ See \spadtype{NumericalQuadrature} for details.

Exports ==> with
  homogenize: (PolyRing,Integer) -> PolyRing

  interpolateFormsForFact: (DIVISOR,List PolyRing) -> List(PolyRing)

  fullDesTree: () -> Void

  fullInfClsPt: () -> Void

  setCurve: PolyRing -> PolyRing

  projectivePoint: List K -> ProjPt

  pointDominateBy : Plc -> ProjPt
    ++ pointDominateBy(pl) returns the projective point dominated
    ++ by the place pl.

  placesAbove: ProjPt -> List Plc

  setSingularPoints: List ProjPt -> List ProjPt

  goppaCode: (DIVISOR,DIVISOR) -> Matrix K

  goppaCode: (DIVISOR,List(Plc)) -> Matrix K

  rationalPlaces: () -> List Plc
    ++ rationalPlaces returns all the rational places of the
    ++ curve defined by the polynomial given to the package.

  theCurve: () -> PolyRing
    ++ theCurve returns the specified polynomial for the package.

  genus: () -> NNI
    ++ genus returns the genus of the curve defined by the polynomial
    ++ given to the package.

```

```

genusNeg: () -> Integer

desingTreeWoFullParam : () -> List DesTree
  ++ desingTreeWoFullParam returns the desingularisation trees at all
  ++ singular points of the curve defined by the polynomial given to
  ++ the package. The local parametrizations are not computed.

desingTree: () -> List DesTree
  ++ desingTree returns the desingularisation trees at all singular
  ++ points of the curve defined by the polynomial given to the package.

rationalPoints: () -> List(ProjPt)

singularPoints: () -> List(ProjPt)
  ++ rationalPoints() returns the singular points of the
  ++ curve defined by the polynomial given to the package.
  ++ If the singular points lie in an extension of the specified
  ++ ground field an error message is issued specifying the extension
  ++ degree needed to find all singular points.

parametrize: (PolyRing,Plc) -> PCS
  ++ parametrize(f,pl) returns a local parametrization of f at the place pl.

lBasis: (DIVISOR,NNI) -> List FRACPOLY

lBasis: DIVISOR -> Record(num:List PolyRing, den: PolyRing)
  ++ lBasis computes a basis associated to the specified divisor

findOrderOfDivisor: (DIVISOR,Integer,Integer) -> _
  Record(ord:Integer,num:PolyRing,den:PolyRing,upTo:Integer)

interpolateForms: (DIVISOR,NNI) -> List(PolyRing)
  ++ interpolateForms(d,n) returns a basis of the interpolate forms of
  ++ degree n of the divisor d.

eval: (PolyRing,Plc) -> K
  ++ eval(f,pl) evaluate f at the place pl.

eval: (PolyRing,PolyRing,Plc) -> K
  ++ eval(f,g,pl) evaluate the function f/g at the place pl.

eval: (FRACPOLY,Plc) -> K
  ++ eval(u,pl) evaluate the function u at the place pl.

evalIfCan: (PolyRing,Plc) -> Union(K,"failed")
  ++ evalIfCan(f,pl) evaluate f at the place pl

```

```

++ (returns "failed" if it is a pole).

evalIfCan: (PolyRing,PolyRing,Plc) -> Union(K,"failed")
++ evalIfCan(f,g,pl) evaluate the function f/g at the place pl
++ (returns "failed" if it is a pole).

evalIfCan: (FRACPOLY,Plc) -> Union(K,"failed")
++ evalIfCan(u,pl) evaluate the function u at the place pl
++ (returns "failed" if it is a pole).

intersectionDivisor: PolyRing -> DIVISOR
++ intersectionDivisor(pol) compute the intersection divisor (the
++ Cartier divisor) of the form pol with the curve. If some
++ intersection points lie in an extension of the ground field,
++ an error message is issued specifying the extension degree
++ needed to find all the intersection points.
++ (If pol is not homogeneous an error message is issued).

adjunctionDivisor: () -> DIVISOR
++ adjunctionDivisor computes the adjunction divisor of the plane
++ curve given by the polynomial set with the function setCurve.

if K has Finite then --should we say LocallyAlgebraicallyClosedField??

LPolynomial: () -> SparseUnivariatePolynomial Integer
++ Returns the L-Polynomial of the curve.

LPolynomial: PI -> SparseUnivariatePolynomial Integer
++ LPolynomial(d) returns the L-Polynomial of the curve in
++ constant field extension of degree d.

classNumber: () -> Integer
++ Returns the class number of the curve.

placesOfDegree: PI -> List Plc
++ placesOfDegree(d) returns all places of degree d of the curve.

numberOfPlacesOfDegree: PI -> Integer
++ returns the number of places of the given degree

numberRatPlacesExtDeg: PI -> Integer
++ numberRatPlacesExtDeg(n) returns the number of rational
++ places in the constant field extension of degree n

numberPlacesDegExtDeg: (PI, PI) -> Integer
++ numberRatPlacesExtDegExtDeg(d, n) returns the number of

```

```

    ++ places of degree d in the constant field extension of degree n

ZetaFunction: () -> UTSZ
    ++ Returns the Zeta function of the curve. Calculated by
    ++ using the L-Polynomial

ZetaFunction: PI -> UTSZ
    ++ Returns the Zeta function of the curve in constant field
    ++ extension. Calculated by using the L-Polynomial

Exp ==> with
  homogenize: (PolyRing,Integer) -> PolyRing

  fullDesTree: () -> Void

  fullInfClsPt: () -> Void

  setCurve: PolyRing -> PolyRing

  translateToOrigin: (PolyRing, ProjPt) -> PolyRing2

  goppaCode: (DIVISOR,DIVISOR) -> Matrix K

  goppaCode: (DIVISOR,List(Plc)) -> Matrix K

  pointDominateBy : Plc -> ProjPt
    ++ pointDominateBy(pl) returns the projective point dominated
    ++ by the place pl.

  placesAbove: ProjPt -> List Plc

  projectivePoint: List DK -> ProjPt

  setSingularPoints: List ProjPt -> List ProjPt

  rationalPlaces: () -> List Plc
    ++ rationalPlaces returns all the rational places of the
    ++ curve defined by the polynomial given to the package.

  theCurve: () -> PolyRing
    ++ theCurve returns the specified polynomial for the package.

```

```

genus: () -> NNI
++ genus returns the genus of the curve defined by the polynomial
++ given to the package.

genusNeg: () -> Integer

desingTreeWoFullParam : () -> List DesTree
++ desingTreeWoFullParam returns the desingularisation trees at all
++ singular points of the curve defined by the polynomial given to
++ the package. The local parametrizations are not computed.

desingTree: () -> List DesTree
++ desingTree returns the desingularisation trees at all singular points
++ of the curve defined by the polynomial given to the package.

rationalPoints: () -> List(ProjPt)

singularPoints: () -> List(ProjPt)
++ rationalPoints() returns the singular points of the
++ curve defined by the polynomial given to the package.
++ If the singular points lie in an extension of the specified
++ ground field an error message is issued specifying the extension
++ degree needed to find all singular points.

parametrize: (PolyRing,Plc) -> PCS
++ parametrize(f,pl) returns a local parametrization of f at the place pl.

lBasis: (DIVISOR,NNI) -> List FracPoly

lBasis: DIVISOR -> Record(num:List PolyRing, den: PolyRing)
++ lBasis computes a basis associated to the specified divisor

findOrderOfDivisor: (DIVISOR,Integer,Integer) -> _
Record(ord:Integer,num:PolyRing,den:PolyRing,upTo:Integer)

interpolateFormsForFact: (DIVISOR,List PolyRing) -> List(PolyRing2)

interpolateForms: (DIVISOR,NNI) -> List(PolyRing)
++ interpolateForms(d,n) returns a basis of the interpolate forms of
++ degree n of the divisor d.

eval: (PolyRing,Plc) -> K
++ eval(f,pl) evaluate f at the place pl.

eval: (PolyRing,PolyRing,Plc) -> K
++ eval(f,g,pl) evaluate the function f/g at the place pl.

```

```

eval: (FracPoly,Plc) -> K
  ++ eval(u,pl) evaluate the function u at the place pl.

evalIfCan: (PolyRing,Plc) -> Union(K,"failed")
  ++ evalIfCan(f,pl) evaluate f at the place pl
  ++ (returns "failed" if it is a pole).

evalIfCan: (PolyRing,PolyRing,Plc) -> Union(K,"failed")
  ++ evalIfCan(f,g,pl) evaluate the function f/g at the place pl
  ++ (returns "failed" if it is a pole).

evalIfCan: (FracPoly,Plc) -> Union(K,"failed")
  ++ evalIfCan(u,pl) evaluate the function u at the place pl
  ++ (returns "failed" if it is a pole).

intersectionDivisor: PolyRing -> DIVISOR
  ++ intersectionDivisor(pol) compute the intersection divisor of the
  ++ form pol with the curve.
  ++ (If pol is not homogeneous an error message is issued).

adjunctionDivisor: () -> DIVISOR
  ++ adjunctionDivisor computes the adjunction divisor of the plane
  ++ curve given by the polynomial defined by setCurve.

if DK has Finite then --should we say LocallyAlgebraicallyClosedField??

LPolynomial: () -> SparseUnivariatePolynomial Integer
  ++ Returns the L-Polynomial of the curve.

LPolynomial: PI -> SparseUnivariatePolynomial Integer
  ++ LPolynomial(d) returns the L-Polynomial of the curve in
  ++ constant field extension of degree d.

classNumber: () -> Integer
  ++ Returns the class number of the curve.

placesOfDegree: PI -> List Plc
  ++ placesOfDegree(d) returns all places of degree d of the
  ++ curve.

numberOfPlacesOfDegree: PI -> Integer
  ++ returns the number of places of the given degree

numberRatPlacesExtDeg: PI -> Integer
  ++ numberRatPlacesExtDeg(n) returns the number of rational

```

```

++ places in the constant field extension of degree n

numberPlacesDegExtDeg: (PI, PI) -> Integer
++ numberRatPlacesExtDegExtDeg(d, n) returns the number of
++ places of degree d in the constant field extension of
++ degree n

ZetaFunction: () -> UTSZ
++ Returns the Zeta function of the curve. Calculated by
++ using the L-Polynomial

ZetaFunction: PI -> UTSZ
++ Returns the Zeta function of the curve in constant field
++ extension. Calculated by using the L-Polynomial

++ Basic Operations: integralBasis, localIntegralBasis
++ Related Domains: WildFunctionFieldIntegralBasis(K,R,UP,F)
++ Also See: FunctionFieldIntegralBasis
++ AMS Classifications:
++ Keywords: function field, finite field, integral basis
++ Examples:
++ References:
++ Description:
++ In this package K is a finite field, R is a ring of univariate
++ polynomials over K, and F is a monogenic algebra over R.
++ We require that F is monogenic, i.e. that \spad{F = K[x,y]/(f(x,y))},
++ because the integral basis algorithm used will factor the polynomial
++ \spad{f(x,y)}. The package provides a function to compute the integral
++ closure of R in the quotient field of F as well as a function to compute
++ a "local integral basis" at a specific prime.

-- modified to conform with new runtime system 06/04/90
-- updated with comments for MB, 02/16/94
-- also cleaned up some unnecessary arguments in regime routine
--
-- MB: In order to allow the rhs to be indeterminate, while working
-- mainly with the parametric variables on the lhs (less number of
-- variables), certain conversions of internal representation from
-- GR to Polynomial R and Fraction Polynomial R are done. At the time
-- of implementation, I thought that this may be more efficient. I
-- have not done any comparison since that requires rewriting the
-- package. My own application needs to call this package quite often,
-- and most computations involves only polynomials in the parametric
-- variables.

-- The 12 modes of psolve are probably not all necessary. Again, I
-- was thinking that if there are many regimes and many ranks, then
-- the output is quite big, and it may be nice to be able to save it
-- and read the results in later to continue computing rather than
-- recomputing. Because of the combinatorial nature of the algorithm
-- (computing all subdeterminants!), it does not take a very big matrix
-- to get into many regimes. But I now have second thoughts of this
-- design, since most of the time, the results are just intermediate,
-- passed to be further processed. On the other hand, there is probably
-- no penalty in leaving the options as is.
```

```
(package PLEQN ParametricLinearEquations)≡
```

```

)abbrev package PLEQN ParametricLinearEquations
++ Author: William Sit, spring 89
++ Description:
++ This package completely solves a parametric linear system of equations
++ by decomposing the set of all parametric values for which the linear
++ system is consistent into a union of quasi-algebraic sets (which need
++ not be irredundant, but most of the time is). Each quasi-algebraic
++ set is described by a list of polynomials that vanish on the set, and
++ a list of polynomials that vanish at no point of the set.
++ For each quasi-algebraic set, the solution of the linear system
++ is given, as a particular solution and a basis of the homogeneous
++ system.
++
++ The parametric linear system should be given in matrix form, with
++ a coefficient matrix and a right hand side vector. The entries
++ of the coefficient matrix and right hand side vector should be
++ polynomials in the parametric variables, over a Euclidean domain
++ of characteristic zero.
++
++ If the system is homogeneous, the right hand side need not be given.
++ The right hand side can also be replaced by an indeterminate vector,
++ in which case, the conditions required for consistency will also be
++ given.
++
++ The package has other facilities for saving results to external
++ files, as well as solving the system for a specified minimum rank.
++ Altogether there are 12 mode maps for psolve, as explained below.

ParametricLinearEquations(R,Var,Expon,GR):
    Declaration == Definition where

    R          : Join(EuclideanDomain, CharacteristicZero)
    -- Warning: does not work if R is a field! because of Fraction R
    Var        : Join(OrderedSet,ConvertibleTo (Symbol))
    Expon       : OrderedAbelianMonoidSup
    GR         : PolynomialCategory(R,Expon,Var)
    F          == Fraction R
    FILE ==> FileCategory
    FNAME ==> FileName
    GB ==> EuclideanGroebnerBasisPackage
    -- GBINTERN ==> GroebnerInternalPackage
    I ==> Integer
    L ==> List
    M ==> Matrix
    NNI ==> NonNegativeInteger
    OUT ==> OutputForm

```

```

P    ==> Polynomial
PI   ==> PositiveInteger
SEG  ==> Segment

V    ==> Vector
mf   ==> MultivariateFactorize(Var,Expon,R,GR)
rp   ==> GB(R,Expon,Var,GR)
gb   ==> GB(R,Expon,Var,GR)
PR   ==> P R
GF   ==> Fraction PR
plift ==> PolynomialCategoryLifting(Expon,Var,R,GR,GF)
Inputmode ==> Integer
groebner ==> euclideanGroebner
redPol ==> euclideanNormalForm

-- MB: The following macros are data structures to store mostly
-- intermediate results
-- Rec stores a subdeterminant with corresponding row and column indices
-- Fgb is a Groebner basis for the ideal generated by the subdeterminants
-- of a given rank.
-- Linsys specifies a linearly independent system of a given system
-- assuming a given rank, using given row and column indices
-- Linsoln stores the solution to the parametric linear system as a basis
-- and a particular solution (for a given regime)
-- Rec2 stores the rank, and a list of subdeterminants of that rank,
-- and a Groebner basis for the ideal they generate.
-- Rec3 stores a regime and the corresponding solution; the regime is
-- given by a list of equations (eqzro) and one inequation (neqzro)
-- describing the quasi-algebraic set which is the regime; the
-- additional consistency conditions due to the rhs is given by wcond.
-- Ranksolns stores a list of regimes and their solutions, and the number
-- of regimes all together.
-- Rec8 (temporary) stores a quasi-algebraic set with an indication
-- whether it is empty (sysok = false) or not (sysok = true).

-- I think psolve should be renamed parametricSolve, or even
-- parametricLinearSolve. On the other hand, may be just solve will do.
-- Please feel free to change it to conform with system conventions.
-- Most psolve routines return a list of regimes and solutions,
-- except those that output to file when the number of regimes is
-- returned instead.
-- This version has been tested on the pc version 1.608 March 13, 1992

++ dmp2rfi(m) converts  $m$  to target domain
dmp2rfi: L GR -> L GF
++ dmp2rfi(l) converts  $l$  to target domain

```

```

se2rfi: L Symbol -> L GF
  ++ se2rfi(l) converts l to target domain
pr2dmp: PR -> GR
  ++ pr2dmp(p) converts p to target domain
hasoln: (Fgb, L GR) -> Rec8
  ++ hasoln(g, l) tests whether the quasi-algebraic set
  ++ defined by  $p = 0$  for  $p$  in  $g$  and  $q \neq 0$  for  $q$  in  $l$ 
  ++ is empty or not and returns a simplified definition
  ++ of the quasi-algebraic set
  -- this is now done in QALGSET package
ParCondList: (M GR, NNI) -> RankConds
  ++ ParCondList(c,r) computes a list of subdeterminants of each
  ++ rank  $\geq r$  of the matrix  $c$  and returns
  ++ a groebner basis for the
  ++ ideal they generate
redpps: (Linsoln, Fgb) -> Linsoln
  ++ redpps(s,g) returns the simplified form of  $s$  after reducing
  ++ modulo a groebner basis  $g$ 

```

## -- LOCAL FUNCTIONS

```

Bisolve: Linsys -> Linsoln
  ++ Bisolve(s) solves the system  $(s.mat) z = s.vec$ 
  ++ for the variables given by the column indices of  $s.cols$ 
  ++ in terms of the other variables and the right hand side  $s.vec$ 
  ++ by assuming that the rank is  $s.rank$ ,
  ++ that the system is consistent, with the linearly
  ++ independent equations indexed by the given row indices  $s.rows$ ;
  ++ the coefficients in  $s.mat$  involving parameters are treated as
  ++ polynomials. Bisolve(s) returns a particular solution to the
  ++ system and a basis of the homogeneous system  $(s.mat) z = 0$ .
factorset: GR -> L GR
  ++ factorset(p) returns the set of irreducible factors of  $p$ .
maxrank: RankConds -> NNI
  ++ maxrank(r) returns the maximum rank in the list  $r$  of regimes
minrank: RankConds -> NNI
  ++ minrank(r) returns the minimum rank in the list  $r$  of regimes
minset: L L GR -> L L GR
  ++ minset(sl) returns the sublist of  $sl$  consisting of the minimal
  ++ lists (with respect to inclusion) in the list  $sl$  of lists
nextSublist: (I, I) -> L L I
  ++ nextSublist(n,k) returns a list of  $k$ -subsets of  $\{1, \dots, n\}$ .
overset?: (L GR, L L GR) -> Boolean
  ++ overset?(s,sl) returns true if  $s$  properly a sublist of a member

```

```

++ of sl; otherwise it returns false
ParCond      : (M GR,NNI) -> Eqns
++ ParCond(m,k) returns the list of all k by k subdeterminants in
++ the matrix m
redmat: (M GR, Fgb) -> M GR
++ redmat(m,g) returns a matrix whose entries are those of m
++ modulo the ideal generated by the groebner basis g
regime: (Rec,M GR,L GF,L L GR,NNI,NNI,Inputmode) -> Rec3
++ regime(y,c, w, p, r, rm, m) returns a regime,
++ a list of polynomials specifying the consistency conditions,
++ a particular solution and basis representing the general
++ solution of the parametric linear system  $c z = w$ 
++ on that regime. The regime returned depends on
++ the subdeterminant y.det and the row and column indices.
++ The solutions are simplified using the assumption that
++ the system has rank r and maximum rank rm. The list p
++ represents a list of list of factors of polynomials in
++ a groebner basis of the ideal generated by higher order
++ subdeterminants, and ius used for the simplification.
++ The mode m
++ distinguishes the cases when the system is homogeneous,
++ or the right hand side is arbitrary, or when there is no
++ new right hand side variables.
sqfree: GR -> GR
++ sqfree(p) returns the product of square free factors of p
inconsistent?: L GR -> Boolean
++ inconsistent?(pl) returns true if the system of equations
++  $p = 0$  for p in pl is inconsistent. It is assumed
++ that pl is a groebner basis.
-- this is needed because of change to
-- EuclideanGroebnerBasisPackage
inconsistent?: L PR -> Boolean
++ inconsistent?(pl) returns true if the system of equations
++  $p = 0$  for p in pl is inconsistent. It is assumed
++ that pl is a groebner basis.
-- this is needed because of change to
-- EuclideanGroebnerBasisPackage

=====
PartialFractionPackage examples
=====
```

When Axiom is given an expression such as:

a:=x+1/(y+1)

it will end up with the result in Fraction Polynomial Integer.

$$\frac{xy + x + 1}{y + 1}$$

We might want it in a partial fraction form. This can be done with:

partialFraction(a,y)\$PFRPAC(INT)

$$x + \frac{1}{y + 1}$$

We can do the same thing with a different variable:

b:=y+1/(x+1)

$$\frac{(x + 1)y + 1}{x + 1}$$

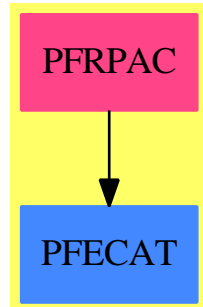

partialFraction(b,x)\$PFRPAC(INT)

$$y + \frac{1}{x + 1}$$

Exports ==> with

```

```

partitions: (I,I,I) -> ST L I
  ++\spad{partitions(p,l,n)} is the stream of partitions
  ++ of n whose number of parts is no greater than p
  ++ and whose largest part is no greater than l.
partitions: I -> ST L I
  ++\spad{partitions(n)} is the stream of all partitions of n.
partitions: (I,I) -> ST L I
  ++\spad{partitions(p,l)} is the stream of all
  ++ partitions whose number of
  ++ parts and largest part are no greater than p and l.
conjugate: L I -> L I
  ++\spad{conjugate(pt)} is the conjugate of the partition pt.
conjugates: ST L I -> ST L I
  ++\spad{conjugates(lp)} is the stream of conjugates of a stream
  ++ of partitions lp.
shuffle: (L I,L I) -> ST L I
  ++\spad{shuffle(l1,l2)} forms the stream of all shuffles of l1
  ++ and l2, i.e. all sequences that can be formed from
  ++ merging l1 and l2.
shufflein: (L I,ST L I) -> ST L I
  ++\spad{shufflein(l,st)} maps shuffle(l,u) on to all
  ++ members u of st, concatenating the results.
sequences: (L I,L I) -> ST L I
  ++\spad{sequences(l1,l2)} is the stream of all sequences that
  ++ can be composed from the multiset defined from
  ++ two lists of integers l1 and l2.
  ++ For example,the pair \spad{([1,2,4],[2,3,5])} represents
  ++ multi-set with 1 \spad{2}, 2 \spad{3}'s, and 4 \spad{5}'s.
sequences: L I -> ST L I
  ++ \spad{sequences([l0,l1,l2,...,ln])} is the set of
  ++ all sequences formed from
  ++ \spad{l0} 0's,\spad{l1} 1's,\spad{l2} 2's,...,\spad{ln} n's.
permutations: I -> ST L I
  ++\spad{permutations(n)} is the stream of permutations
  ++ formed from \spad{1,2,3,...,n}.

```

#### Exports:

assert constant multiple optional

*(package PMASS PatternMatchAssertions)≡*

)abbrev package PMASS PatternMatchAssertions

++ Author: Manuel Bronstein

++ Date Created: 21 Mar 1989

++ Date Last Updated: 23 May 1990

++ Keywords: pattern, matching.

++ Description:

++ Attaching assertions to symbols for pattern matching.

PatternMatchAssertions(): Exports == Implementation where  
FE ==> Expression Integer

Exports ==> with

assert : (Symbol, String) -> FE

++ assert(x, s) makes the assertion s about x.

constant: Symbol -> FE

++ constant(x) tells the pattern matcher that x should

++ match only the symbol 'x and no other quantity.

optional: Symbol -> FE

++ optional(x) tells the pattern matcher that x can match

++ an identity (0 in a sum, 1 in a product or exponentiation).;

multiple: Symbol -> FE

++ multiple(x) tells the pattern matcher that x should

++ preferably match a multi-term quantity in a sum or product.

++ For matching on lists, multiple(x) tells the pattern matcher

++ that x should match a list instead of an element of a list.

Implementation ==> add

```

import FunctionSpaceAssertions(Integer, FE)

constant x == constant(x::FE)
multiple x == multiple(x::FE)
optional x == optional(x::FE)
assert(x, s) == assert(x::FE, s)

=====
Permanent examples
=====
```

The package Permanent provides the function permanent for square matrices. The permanent of a square matrix can be computed in the same way as the determinant by expansion of minors except that for the permanent the sign for each element is 1, rather than being 1 if the row plus column indices is positive and -1 otherwise. This function is much more difficult to compute efficiently than the determinant. An example of the use of permanent is the calculation of the n-th derangement number, defined to be the number of different possibilities for n couples to dance but never with their own spouse.

Consider an n by n matrix with entries 0 on the diagonal and 1 elsewhere. Think of the rows as one-half of each couple (for example, the males) and the columns the other half. The permanent of such a matrix gives the desired derangement number.

```
kn n ==
  r : MATRIX INT := new(n,n,1)
  for i in 1..n repeat
    r.i.i := 0
  r
```

Here are some derangement numbers, which you see grow quite fast.

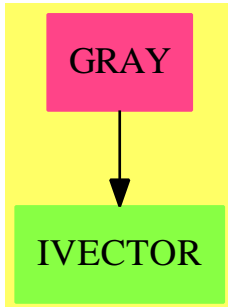

```
permanent(kn(5) :: SQMATRIX(5,INT))

[permanent(kn(n) :: SQMATRIX(n,INT)) for n in 1..13]
```

  PI ==> PositiveInteger

```

```

GRAY ==> GrayCode

public ==> with

permanent: SM -> R
++ permanent(x) computes the permanent of a square matrix x.
++ The permanent is equivalent to
++ the \spadfun{determinant} except that coefficients have
++ no change of sign. This function
++ is much more difficult to compute than the
++ determinant. The formula used is by H.J. Ryser,
++ improved by [Nijenhuis and Wilf, Ch. 19].
++ Note that permanent(x) choose one of three algorithms, depending
++ on the underlying ring R and on n, the number of rows (and
++ columns) of x:\br
++ if 2 has an inverse in R we can use the algorithm of
++ [Nijenhuis and Wilf, ch.19,p.158]; if 2 has no inverse,
++ some modifications are necessary:\br
++ if n > 6 and R is an integral domain with characteristic
++ different from 2 (the algorithm works if and only 2 is not a
++ zero-divisor of R and characteristic() $R \neq 2$ ,
++ but how to check that for any given R ?),
++ the local function permanent2 is called;\br
++ else, the local function permanent3 is called
++ (works for all commutative rings R).

++ is the direct product of cyclic groups with order ni.
cyclicGroup:         PI          -> PERMGRP I
++ cyclicGroup(n) constructs the cyclic group of order n acting
++ on the integers 1,...,n.
cyclicGroup:         L I          -> PERMGRP I
++ cyclicGroup([i1,...,ik]) constructs the cyclic group of
++ order k acting on the integers i1,...,ik.
++ Note that duplicates in the list will be removed.
dihedralGroup:       PI          -> PERMGRP I
++ dihedralGroup(n) constructs the dihedral group of order 2n
++ acting on integers 1,...,N.
dihedralGroup:       L I          -> PERMGRP I
++ dihedralGroup([i1,...,ik]) constructs the dihedral group of

```

```

++ order 2k acting on the integers out of i1,...,ik.
++ Note that duplicates in the list will be removed.
mathieu11:      L I      -> PERMGRP I
++ mathieu11(li) constructs the mathieu group acting on the 11
++ integers given in the list li.
++ Note that duplicates in the list will be removed.
++ error, if li has less or more than 11 different entries.
mathieu11:      ()      -> PERMGRP I
++ mathieu11 constructs the mathieu group acting on the
++ integers 1,...,11.
mathieu12:      L I      -> PERMGRP I
++ mathieu12(li) constructs the mathieu group acting on the 12
++ integers given in the list li.
++ Note that duplicates in the list will be removed
++ Error: if li has less or more than 12 different entries.
mathieu12:      ()      -> PERMGRP I
++ mathieu12 constructs the mathieu group acting on the
++ integers 1,...,12.
mathieu22:      L I      -> PERMGRP I
++ mathieu22(li) constructs the mathieu group acting on the 22
++ integers given in the list li.
++ Note that duplicates in the list will be removed.
++ Error: if li has less or more than 22 different entries.
mathieu22:      ()      -> PERMGRP I
++ mathieu22 constructs the mathieu group acting on the
++ integers 1,...,22.
mathieu23:      L I      -> PERMGRP I
++ mathieu23(li) constructs the mathieu group acting on the 23
++ integers given in the list li.
++ Note that duplicates in the list will be removed.
++ Error: if li has less or more than 23 different entries.
mathieu23:      ()      -> PERMGRP I
++ mathieu23 constructs the mathieu group acting on the
++ integers 1,...,23.
mathieu24:      L I      -> PERMGRP I
++ mathieu24(li) constructs the mathieu group acting on the 24
++ integers given in the list li.
++ Note that duplicates in the list will be removed.
++ Error: if li has less or more than 24 different entries.
mathieu24:      ()      -> PERMGRP I
++ mathieu24 constructs the mathieu group acting on the
++ integers 1,...,24.
janko2:         L I      -> PERMGRP I
++ janko2(li) constructs the janko group acting on the 100
++ integers given in the list li.
++ Note that duplicates in the list will be removed.

```

```

++ Error: if li has less or more than 100 different entries
janko2:      ()      -> PERMGRP I
++ janko2 constructs the janko group acting on the
++ integers 1,...,100.
rubiksGroup:      ()      -> PERMGRP I
++ rubiksGroup constructs the permutation group representing
++ Rubic's Cube acting on integers 10*i+j for
++ 1 <= i <= 6, 1 <= j <= 8.
++ The faces of Rubik's Cube are labelled in the obvious way
++ Front, Right, Up, Down, Left, Back and numbered from 1 to 6
++ in this given ordering, the pieces on each face
++ (except the unmoveable center piece) are clockwise numbered
++ from 1 to 8 starting with the piece in the upper left
++ corner. The moves of the cube are represented as permutations
++ on these pieces, represented as a two digit
++ integer ij where i is the numer of theface (1 to 6)
++ and j is the number of the piece on this face.
++ The remaining ambiguities are resolved by looking
++ at the 6 generators, which represent a 90 degree turns of the
++ faces, or from the following pictorial description.
++ Permutation group representing Rubic's Cube acting on integers
++ 10*i+j for 1 <= i <= 6, 1 <= j <=8.
++
++ \begin{verbatim}
++ Rubik's Cube:  +-----+ +--- B   where: marks Side # :
++                /  U    /|/
++                /      / |      F(ront)    <->    1
++      L --> +-----+ R|      R(ight)    <->    2
++                |      |  +      U(p)      <->    3
++                |  F  |  /      D(own)    <->    4
++                |      | /      L(eft)    <->    5
++                +-----+      B(ack)    <->    6
++                ^
++                |
++                D
++
++ The Cube's surface:
++
++                +----+
++                |567|
++                |4U8|
++                |321|
++      +----+----+----+
++      |781|123|345|
++      |6L2|8F4|2R6|
++      |543|765|187|

```

The pieces on each side  
(except the unmoveable center  
piece) are clockwise numbered  
from 1 to 8 starting with the  
piece in the upper left  
corner (see figure on the  
left). The moves of the cube  
are represented as  
permutations on these pieces.

```

++          +---+---+---+          Each of the pieces is
++          |123|                    represented as a two digit
++          |8D4|                    integer ij where i is the
++          |765|                    # of the side ( 1 to 6 for
++          +---+                    F to B (see table above ))
++          |567|                    and j is the # of the piece.
++          |4B8|
++          |321|
++          +---+
++ \end{verbatim}
youngGroup:      L I      -> PERMGRP I
++ youngGroup([n1,...,nk]) constructs the direct product of the
++ symmetric groups Sn1,...,Snk.
youngGroup:      Partition      -> PERMGRP I
++ youngGroup(lambda) constructs the direct product of the symmetric
++ groups given by the parts of the partition lambda.

++ Related Constructors: GroebnerPackage

++ Also See:

++ AMS Classifications:

++ Keywords: groebner basis, polynomial ideals

++ References:

++ Description:

++ Groebner functions for P F

++ This package is an interface package to the groebner basis

++ package which allows you to compute groebner bases for polynomials

++ in either lexicographic ordering or total degree ordering refined

++ by reverse lex. The input is the ordinary polynomial type which

++ is internally converted to a type with the required ordering.

++ The resulting grobner basis is converted back to ordinary polynomials.

++ The ordering among the variables is controlled by an explicit list

++ of variables which is passed as a second argument. The coefficient

++ domain is allowed to be any gcd domain, but the groebner basis is

++ computed as if the polynomials were over a field.

PolyGroebner(F) : C == T

  bernoulli : I -> SUP RN
  ++ bernoulli(n) returns the nth Bernoulli polynomial \spad{B[n](x)}.
```

```

++ Bernoulli polynomials denoted \spad{B(n,x)} computed by solving the
++ differential equation \spad{differentiate(B(n,x),x) = n B(n-1,x)} where
++ \spad{B(0,x) = 1} and initial condition comes from \spad{B(n) = B(n,0)}.
chebyshevT: I -> SUP I
++ chebyshevT(n) returns the nth Chebyshev polynomial \spad{T[n](x)}.
++ Note that Chebyshev polynomials of the first kind,
++ denoted \spad{T[n](x)},
++ computed from the two term recurrence. The generating function
++ \spad{(1-t*x)/(1-2*t*x+t**2) = sum(T[n](x)*t**n, n=0..infinity)}.
chebyshevU: I -> SUP I
++ chebyshevU(n) returns the nth Chebyshev polynomial \spad{U[n](x)}.
++ Note that Chebyshev polynomials of the second kind,
++ denoted \spad{U[n](x)},
++ computed from the two term recurrence. The generating function
++ \spad{1/(1-2*t*x+t**2) = sum(T[n](x)*t**n, n=0..infinity)}.
cyclotomic: I -> SUP I
++ cyclotomic(n) returns the nth cyclotomic polynomial \spad{phi[n](x)}.
++ Note that \spad{phi[n](x)} is the factor of \spad{x**n - 1} whose roots
++ are the primitive nth roots of unity.
euler      : I -> SUP RN
++ euler(n) returns the nth Euler polynomial \spad{E[n](x)}.
++ Note that Euler polynomials denoted \spad{E(n,x)} computed by solving
++ the differential equation
++ \spad{differentiate(E(n,x),x) = n E(n-1,x)} where
++ \spad{E(0,x) = 1} and initial condition comes
++ from \spad{E(n) = 2**n E(n,1/2)}.
fixedDivisor: SUP I -> I
++ fixedDivisor(a) for \spad{a(x)} in \spad{Z[x]} is the largest integer
++ f such that f divides \spad{a(x=k)} for all integers k.
++ Note that fixed divisor of \spad{a} is
++ \spad{reduce(gcd,[a(x=k) for k in 0..degree(a)])}.
hermite    : I -> SUP I
++ hermite(n) returns the nth Hermite polynomial \spad{H[n](x)}.
++ Note that Hermite polynomials, denoted \spad{H[n](x)}, are computed from
++ the two term recurrence. The generating function is:
++ \spad{exp(2*t*x-t**2) = sum(H[n](x)*t**n/n!, n=0..infinity)}.
laguerre   : I -> SUP I
++ laguerre(n) returns the nth Laguerre polynomial \spad{L[n](x)}.
++ Note that Laguerre polynomials, denoted \spad{L[n](x)}, are computed
++ from the two term recurrence. The generating function is:
++ \spad{exp(x*t/(t-1))/(1-t) = sum(L[n](x)*t**n/n!, n=0..infinity)}.
legendre   : I -> SUP RN
++ legendre(n) returns the nth Legendre polynomial \spad{P[n](x)}.
++ Note that Legendre polynomials, denoted \spad{P[n](x)}, are computed
++ from the two term recurrence. The generating function is:
++ \spad{1/sqrt(1-2*t*x+t**2) = sum(P[n](x)*t**n, n=0..infinity)}.

++ Description:
++ This package provides modest routines for polynomial system solving.
++ The aim of many of the operations of this package is to remove certain
++ factors in some polynomials in order to avoid unnecessary computations
++ in algorithms involving splitting techniques by partial factorization.

Exports == with

removeRedundantFactors: LP -> LP
++ \axiom{removeRedundantFactors(lp)} returns \axiom{lq} such that if
++ \axiom{lp = [p1,...,pn]} and \axiom{lq = [q1,...,qm]}
++ then the product \axiom{p1*p2*...*pn} vanishes iff the product \axiom{
++ and the product of degrees of the \axiom{qi} is not greater than
++ the one of the \axiom{pj}, and no polynomial in \axiom{lq}
++ divides another polynomial in \axiom{lq}. In particular,
++ polynomials lying in the base ring \axiom{R} are removed.
++ Moreover, \axiom{lq} is sorted w.r.t \axiom{infRittWu?}.
++ Furthermore, if R is gcd-domain, the polynomials in \axiom{lq} are
++ pairwise without common non trivial factor.
removeRedundantFactors: (P,P) -> LP
++ \axiom{removeRedundantFactors(p,q)} returns the same as
++ \axiom{removeRedundantFactors([p,q])}
removeSquaresIfCan : LP -> LP
++ \axiom{removeSquaresIfCan(lp)} returns
++ \axiom{removeDuplicates [squareFreePart(p)$P for p in lp]}
++ if \axiom{R} is gcd-domain else returns \axiom{lp}.
unprotectedRemoveRedundantFactors: (P,P) -> LP
++ \axiom{unprotectedRemoveRedundantFactors(p,q)} returns the same as

```

```

++ \axiom{removeRedundantFactors(p,q)} but does assume that neither
++ \axiom{p} nor \axiom{q} lie in the base ring \axiom{R} and assumes that
++ \axiom{infRittWu?(p,q)} holds. Moreover, if \axiom{R} is gcd-domain,
++ then \axiom{p} and \axiom{q} are assumed to be square free.
removeRedundantFactors: (LP,P) -> LP
++ \axiom{removeRedundantFactors(lp,q)} returns the same as
++ \axiom{removeRedundantFactors(cons(q,lp))} assuming
++ that \axiom{removeRedundantFactors(lp)} returns \axiom{lp}
++ up to replacing some polynomial \axiom{pj} in \axiom{lp}
++ by some some polynomial \axiom{qj} associated to \axiom{pj}.
removeRedundantFactors : (LP,LP) -> LP
++ \axiom{removeRedundantFactors(lp,lq)} returns the same as
++ \axiom{removeRedundantFactors(concat(lp,lq))} assuming
++ that \axiom{removeRedundantFactors(lp)} returns \axiom{lp}
++ up to replacing some polynomial \axiom{pj} in \axiom{lp}
++ by some polynomial \axiom{qj} associated to \axiom{pj}.
removeRedundantFactors : (LP,LP,(LP -> LP)) -> LP
++ \axiom{removeRedundantFactors(lp,lq,remOp)} returns the same as
++ \axiom{concat(remOp(removeRoughlyRedundantFactorsInPols(lp,lq)),lq)}
++ assuming that \axiom{remOp(lq)} returns \axiom{lq} up to similarity.
certainlySubVariety? : (LP,LP) -> B
++ \axiom{certainlySubVariety?(newlp,lp)} returns true iff for every \axiom{p}
++ in \axiom{lp} the remainder of \axiom{p} by \axiom{newlp} using the division algo
++ of Groebner techniques is zero.
possiblyNewVariety? : (LP, List LP) -> B
++ \axiom{possiblyNewVariety?(newlp,llp)} returns true iff for every \axiom{lp}
++ in \axiom{llp} certainlySubVariety?(newlp,lp) does not hold.
probablyZeroDim?: LP -> B
++ \axiom{probablyZeroDim?(lp)} returns true iff the number of polynomials
++ in \axiom{lp} is not smaller than the number of variables occurring
++ in these polynomials.
selectPolynomials : ((P -> B),LP) -> Record(goodPols:LP,badPols:LP)
++ \axiom{selectPolynomials(pred?,ps)} returns \axiom{gps,bps} where
++ \axiom{gps} is a list of the polynomial \axiom{p} in \axiom{ps}
++ such that \axiom{pred?(p)} holds and \axiom{bps} are the other ones.
selectOrPolynomials : (List (P -> B),LP) -> Record(goodPols:LP,badPols:LP)
++ \axiom{selectOrPolynomials(lpred?,ps)} returns \axiom{gps,bps} where
++ \axiom{gps} is a list of the polynomial \axiom{p} in \axiom{ps}
++ such that \axiom{pred?(p)} holds for some \axiom{pred?} in \axiom{lpred?}
++ and \axiom{bps} are the other ones.
selectAndPolynomials : (List (P -> B),LP) -> Record(goodPols:LP,badPols:LP)
++ \axiom{selectAndPolynomials(lpred?,ps)} returns \axiom{gps,bps} where
++ \axiom{gps} is a list of the polynomial \axiom{p} in \axiom{ps}
++ such that \axiom{pred?(p)} holds for every \axiom{pred?} in \axiom{lpred?}
++ and \axiom{bps} are the other ones.
quasiMonicPolynomials : LP -> Record(goodPols:LP,badPols:LP)

```

```

++ \axiom{quasiMonicPolynomials(lp)} returns \axiom{qmps,nqmps} where
++ \axiom{qmps} is a list of the quasi-monic polynomials in \axiom{lp}
++ and \axiom{nqmps} are the other ones.
univariate? : P -> B
++ \axiom{univariate?(p)} returns true iff \axiom{p} involves one and
++ only one variable.
univariatePolynomials : LP -> Record(goodPols:LP,badPols:LP)
++ \axiom{univariatePolynomials(lp)} returns \axiom{ups,nups} where
++ \axiom{ups} is a list of the univariate polynomials,
++ and \axiom{nups} are the other ones.
linear? : P -> B
++ \axiom{linear?(p)} returns true iff \axiom{p} does not lie
++ in the base ring \axiom{R} and has main degree \axiom{1}.
linearPolynomials : LP -> Record(goodPols:LP,badPols:LP)
++ \axiom{linearPolynomials(lp)} returns \axiom{lps,nlps} where
++ \axiom{lps} is a list of the linear polynomials in lp,
++ and \axiom{nlps} are the other ones.
bivariate? : P -> B
++ \axiom{bivariate?(p)} returns true iff \axiom{p} involves two and
++ only two variables.
bivariatePolynomials : LP -> Record(goodPols:LP,badPols:LP)
++ \axiom{bivariatePolynomials(lp)} returns \axiom{bps,nbps} where
++ \axiom{bps} is a list of the bivariate polynomials,
++ and \axiom{nbps} are the other ones.
removeRoughlyRedundantFactorsInPols : (LP, LP) -> LP
++ \axiom{removeRoughlyRedundantFactorsInPols(lp,lf)} returns
++ \axiom{newlp} where \axiom{newlp} is obtained from \axiom{lp}
++ by removing in every polynomial \axiom{p} of \axiom{lp}
++ any occurrence of a polynomial \axiom{f} in \axiom{lf}.
++ This may involve a lot of exact-quotients computations.
removeRoughlyRedundantFactorsInPols : (LP, LP,B) -> LP
++ \axiom{removeRoughlyRedundantFactorsInPols(lp,lf,opt)} returns
++ the same as \axiom{removeRoughlyRedundantFactorsInPols(lp,lf)}
++ if \axiom{opt} is \axiom{false} and if the previous operation
++ does not return any non null and constant polynomial,
++ else return \axiom{[1]}.
removeRoughlyRedundantFactorsInPol : (P,LP) -> P
++ \axiom{removeRoughlyRedundantFactorsInPol(p,lf)} returns the same as
++ removeRoughlyRedundantFactorsInPols([p],lf,true)
interReduce: LP -> LP
++ \axiom{interReduce(lp)} returns \axiom{lq} such that \axiom{lp}
++ and \axiom{lq} generate the same ideal and no polynomial
++ in \axiom{lq} is reducible by the others in the sense
++ of Groebner bases. Since no assumptions are required
++ the result may depend on the ordering the reductions are
++ performed.

```

```

roughBasicSet: LP -> Union(Record(bas:T,top:LP),"failed")
  ++ \axiom{roughBasicSet(lp)} returns the smallest (with Ritt-Wu
  ++ ordering) triangular set contained in \axiom{lp}.
crushedSet: LP -> LP
  ++ \axiom{crushedSet(lp)} returns \axiom{lp} such that \axiom{lp} and
  ++ and \axiom{lp} generate the same ideal and no rough basic
  ++ sets reduce (in the sense of Groebner bases) the other
  ++ polynomials in \axiom{lp}.
rewriteSetByReducingWithParticularGenerators : (LP,(P->B),((P,P)->B),((P,P)->P)) -> LP
  ++ \axiom{rewriteSetByReducingWithParticularGenerators(lp,pred?,redOp?,redOp)}
  ++ returns \axiom{lp} where \axiom{lp} is computed by the following
  ++ algorithm. Chose a basic set w.r.t. the reduction-test \axiom{redOp?}
  ++ among the polynomials satisfying property \axiom{pred?},
  ++ if it is empty then leave, else reduce the other polynomials by
  ++ this basic set w.r.t. the reduction-operation \axiom{redOp}.
  ++ Repeat while another basic set with smaller rank can be computed.
  ++ See code. If \axiom{pred?} is \axiom{quasiMonic?} the ideal is unchanged.
rewriteIdealWithQuasiMonicGenerators : (LP,((P,P)->B),((P,P)->P)) -> LP
  ++ \axiom{rewriteIdealWithQuasiMonicGenerators(lp,redOp?,redOp)} returns
  ++ \axiom{lp} where \axiom{lp} and \axiom{lp} generate
  ++ the same ideal in \axiom{R-1 P} and \axiom{lp}
  ++ has rank not higher than the one of \axiom{lp}.
  ++ Moreover, \axiom{lp} is computed by reducing \axiom{lp}
  ++ w.r.t. some basic set of the ideal generated by
  ++ the quasi-monic polynomials in \axiom{lp}.
if R has GcdDomain
then
  squareFreeFactors : P -> LP
    ++ \axiom{squareFreeFactors(p)} returns the square-free factors of \axiom{p}
    ++ over \axiom{R}
  univariatePolynomialsGcds : LP -> LP
    ++ \axiom{univariatePolynomialsGcds(lp)} returns \axiom{lg} where
    ++ \axiom{lg} is a list of the gcds of every pair in \axiom{lp}
    ++ of univariate polynomials in the same main variable.
  univariatePolynomialsGcds : (LP,B) -> LP
    ++ \axiom{univariatePolynomialsGcds(lp,opt)} returns the same as
    ++ \axiom{univariatePolynomialsGcds(lp)} if \axiom{opt} is
    ++ \axiom{false} and if the previous operation does not return
    ++ any non null and constant polynomial, else return \axiom{[1]}.
  removeRoughlyRedundantFactorsInContents : (LP, LP) -> LP
    ++ \axiom{removeRoughlyRedundantFactorsInContents(lp,lf)} returns
    ++ \axiom{newlp} where \axiom{newlp} is obtained from \axiom{lp}
    ++ by removing in the content of every polynomial of \axiom{lp}
    ++ any occurrence of a polynomial \axiom{f} in \axiom{lf}. Moreover,
    ++ squares over \axiom{R} are first removed in the content
    ++ of every polynomial of \axiom{lp}.

```

```

removeRedundantFactorsInContents : (LP, LP) -> LP
  ++ \axiom{removeRedundantFactorsInContents(lp,lf)} returns \axiom{newlp}
  ++ where \axiom{newlp} is obtained from \axiom{lp} by removing
  ++ in the content of every polynomial of \axiom{lp} any non trivial
  ++ factor of any polynomial \axiom{f} in \axiom{lf}. Moreover,
  ++ squares over \axiom{R} are first removed in the content
  ++ of every polynomial of \axiom{lp}.
removeRedundantFactorsInPols : (LP, LP) -> LP
  ++ \axiom{removeRedundantFactorsInPols(lp,lf)} returns \axiom{newlp}
  ++ where \axiom{newlp} is obtained from \axiom{lp} by removing
  ++ in every polynomial \axiom{p} of \axiom{lp} any non trivial
  ++ factor of any polynomial \axiom{f} in \axiom{lf}. Moreover,
  ++ squares over \axiom{R} are first removed in every
  ++ polynomial \axiom{lp}.
if (R has EuclideanDomain) and (R has CharacteristicZero)
then
  irreducibleFactors : LP -> LP
    ++ \axiom{irreducibleFactors(lp)} returns \axiom{lf} such that if
    ++ \axiom{lp} = [p1,...,pn] and \axiom{lf} = [f1,...,fm] then
    ++ \axiom{p1*p2*...*pn=0} means \axiom{f1*f2*...*fm=0}, and the \axiom{f}
    ++ are irreducible over \axiom{R} and are pairwise distinct.
  lazyIrreducibleFactors : LP -> LP
    ++ \axiom{lazyIrreducibleFactors(lp)} returns \axiom{lf} such that if
    ++ \axiom{lp} = [p1,...,pn] and \axiom{lf} = [f1,...,fm] then
    ++ \axiom{p1*p2*...*pn=0} means \axiom{f1*f2*...*fm=0}, and the \axiom{f}
    ++ are irreducible over \axiom{R} and are pairwise distinct.
    ++ The algorithm tries to avoid factorization into irreducible
    ++ factors as far as possible and makes previously use of gcd
    ++ techniques over \axiom{R}.
  removeIrreducibleRedundantFactors : (LP, LP) -> LP
    ++ \axiom{removeIrreducibleRedundantFactors(lp,lq)} returns the same
    ++ as \axiom{irreducibleFactors(concat(lp,lq))} assuming
    ++ that \axiom{irreducibleFactors(lp)} returns \axiom{lp}
    ++ up to replacing some polynomial \axiom{pj} in \axiom{lp}
    ++ by some polynomial \axiom{qj} associated to \axiom{pj}.

)abbrev package SOLVEFOR PolynomialSolveByFormulas
-- Current fields with "***": (%, RationalNumber) -> % are
-- ComplexFloat, RadicalExtension(K) and RationalRadical
-- SMW June 86, BMT Sept 93
++ Description:
++ This package factors the formulas out of the general solve code,
++ allowing their recursive use over different domains.
++ Care is taken to introduce few radicals so that radical extension
++ domains can more easily simplify the results.

++ Date Last Updated: November 1993, (P.Gianni)
++ Basic Functions:
++ Related Constructors:
++ Also See:
++ AMS Classifications:
++ Keywords:
++ References:
++ Description:
++ This package computes square-free decomposition of multivariate
++ polynomials over a coefficient ring which is an arbitrary gcd domain.
++ The requirement on the coefficient domain guarantees that the
++ \spadfun{content} can be
++ removed so that factors will be primitive as well as square-free.
++ Over an infinite ring of finite characteristic, it may not be possible to
++ guarantee that the factors are square-free.

```

```

++ Author: Manuel Bronstein

++ Date Created: 1 March 1991

++ Date Last Updated: 1 February 1994

++ Description:

++ \spad{PrimitiveRatDE} provides functions for in-field solutions of linear  
++ ordinary differential equations, in the transcendental case.

++ The derivation to use is given by the parameter \spad{L}.

PrimitiveRatDE(F, UP, L, LQ): Exports == Implementation where

F : Join(Field, CharacteristicZero, RetractableTo Fraction Integer)

UP : UnivariatePolynomialCategory F

L : LinearOrdinaryDifferentialOperatorCategory UP

LQ : LinearOrdinaryDifferentialOperatorCategory Fraction UP

N ==> NonNegativeInteger

Z ==> Integer

RF ==> Fraction UP

UP2 ==> SparseUnivariatePolynomial UP

REC ==> Record(center:UP, equation:UP)

Exports ==> with

denomLODE: (L, RF) -> Union(UP, "failed")

++ denomLODE(op, g) returns a polynomial d such that

++ any rational solution of \spad{op y = g}

++ is of the form \spad{p/d} for some polynomial p, and

++ "failed", if the equation has no rational solution.

```

denomLODE: (L, List RF) -> UP
  ++ denomLODE(op, [g1,...,gm]) returns a polynomial
  ++ d such that any rational solution of \spad{op y = c1 g1 + ... + cm gm}
  ++ is of the form \spad{p/d} for some polynomial p.
indicialEquations: L -> List REC
  ++ indicialEquations op returns \spad{[[d1,e1],...,[dq,eq]]} where
  ++ the \spad{d_i}'s are the affine singularities of \spad{op},
  ++ and the \spad{e_i}'s are the indicial equations at each \spad{d_i}.
indicialEquations: (L, UP) -> List REC
  ++ indicialEquations(op, p) returns \spad{[[d1,e1],...,[dq,eq]]} where
  ++ the \spad{d_i}'s are the affine singularities of \spad{op}
  ++ above the roots of \spad{p},
  ++ and the \spad{e_i}'s are the indicial equations at each \spad{d_i}.

++ denomRicDE(op) returns a polynomial \spad{d} such that any rational
++ solution of the associated Riccati equation of \spad{op y = 0} is
++ of the form \spad{p/d + q'/q + r} for some polynomials p and q
++ and a reduced r. Also, \spad{deg(p) < deg(d)} and {gcd(d,q) = 1}.
leadingCoefficientRicDE: L -> List REC
++ leadingCoefficientRicDE(op) returns
++ \spad{[[m1, p1], [m2, p2], ... , [mk, pk]]} such that the polynomial
++ part of any rational solution of the associated Riccati equation of
++ \spad{op y = 0} must have degree mj for some j, and its leading
++ coefficient is then a zero of pj. In addition, \spad{m1>m2> ... >mk}.
constantCoefficientRicDE: (L, UP -> List F) -> List CNT
++ constantCoefficientRicDE(op, ric) returns
++ \spad{[[a1, L1], [a2, L2], ... , [ak, Lk]]} such that any rational
++ solution with no polynomial part of the associated Riccati equation of
++ \spad{op y = 0} must be one of the ai's in which case the equation for
++ \spad{z = y e^{-int ai}} is \spad{Li z = 0}.
++ \spad{ric} is a Riccati equation solver over \spad{F}, whose input
++ is the associated linear equation.
polyRicDE: (L, UP -> List F) -> List POL
++ polyRicDE(op, zeros) returns
++ \spad{[[p1, L1], [p2, L2], ... , [pk, Lk]]} such that the polynomial
++ part of any rational solution of the associated Riccati equation of
++ \spad{op y=0} must be one of the pi's (up to the constant coefficient),
++ in which case the equation for \spad{z=y e^{-int p}} is \spad{Li z=0}.
++ \spad{zeros} is a zero finder in \spad{UP}.
singRicDE: (L, (UP, UP2) -> List UP, UP -> Factored UP) -> List FRC
++ singRicDE(op, zeros, ezfactor) returns
++ \spad{[[f1, L1], [f2, L2], ... , [fk, Lk]]} such that the singular
++ part of any rational solution of the associated Riccati equation of
++ \spad{op y=0} must be one of the fi's (up to the constant coefficient),
++ in which case the equation for \spad{z=y e^{-int p}} is \spad{Li z=0}.
++ \spad{zeros(C(x),H(x,y))} returns all the \spad{P_i(x)}'s such that
++ \spad{H(x,P_i(x)) = 0 modulo C(x)}.
++ Argument \spad{ezfactor} is a factorisation in \spad{UP},
++ not necessarily into irreducibles.
changeVar: (L, UP) -> L
++ changeVar(+/[ai D^i], a) returns the operator \spad{+/[ai (D+a)^i]}.
changeVar: (L, RF) -> L
++ changeVar(+/[ai D^i], a) returns the operator \spad{+/[ai (D+a)^i]}.

## 17.69 package PRS PseudoRemainderSequence

The package constructor **PseudoRemainderSequence** provides efficient algorithms by Lionel Ducos (University of Poitiers, France) for computing sub-resultants. This leads to a speed up in many places in Axiom where sub-resultants are computed (polynomial system solving, algebraic factorization, integration).

### 17.69.1 PseudoRemainderSequence (PRS)

++ Description:
++ This package contains some functions: discriminant, resultant,
++ subResultantGcd, chainSubResultants, degreeSubResultant, lastSubResultant,
++ resultantEuclidean, subResultantGcdEuclidean, semiSubResultantGcdEuclidean1,
++ semiSubResultantGcdEuclidean2\br
++ These procedures come from improvements of the subresultants algorithm.

PseudoRemainderSequence(R, polR) : Specification == Implementation where
  R : IntegralDomain
  polR : UnivariatePolynomialCategory(R)
  NNI ==> NonNegativeInteger
  LC ==> leadingCoefficient

Specification == with
  resultant : (polR, polR) -> R
    ++ \axiom{resultant(P, Q)} returns the resultant
    ++ of \axiom{P} and \axiom{Q}

  resultantEuclidean : (polR, polR) ->
    Record(coef1 : polR, coef2 : polR, resultant : R)
    ++ \axiom{resultantEuclidean(P,Q)} carries out the equality
    ++ \axiom{coef1*P + coef2*Q = resultant(P,Q)}

  semiResultantEuclidean2 : (polR, polR) ->
    Record(coef2 : polR, resultant : R)
    ++ \axiom{semiResultantEuclidean2(P,Q)} carries out the equality
    ++ \axiom{...P + coef2*Q = resultant(P,Q)}.
    ++ Warning. \axiom{degree(P) >= degree(Q)}.

  semiResultantEuclidean1 : (polR, polR) ->
    Record(coef1 : polR, resultant : R)
    ++ \axiom{semiResultantEuclidean1(P,Q)} carries out the equality
    ++ \axiom{coef1.P + ? Q = resultant(P,Q)}.

  indiceSubResultant : (polR, polR, NNI) -> polR
    ++ \axiom{indiceSubResultant(P, Q, i)} returns
    ++ the subresultant of indice \axiom{i}

```

```

indiceSubResultantEuclidean : (polR, polR, NNI) ->
    Record(coef1 : polR, coef2 : polR, subResultant : polR)
    ++ \axiom{indiceSubResultant(P, Q, i)} returns
    ++ the subresultant \axiom{S_i(P,Q)} and carries out the equality
    ++ \axiom{coef1*P + coef2*Q = S_i(P,Q)}

semiIndiceSubResultantEuclidean : (polR, polR, NNI) ->
    Record(coef2 : polR, subResultant : polR)
    ++ \axiom{semiIndiceSubResultantEuclidean(P, Q, i)} returns
    ++ the subresultant \axiom{S_i(P,Q)} and carries out the equality
    ++ \axiom{...P + coef2*Q = S_i(P,Q)}
    ++ Warning. \axiom{degree(P) >= degree(Q)}.

degreeSubResultant : (polR, polR, NNI) -> polR
    ++ \axiom{degreeSubResultant(P, Q, d)} computes
    ++ a subresultant of degree \axiom{d}.

degreeSubResultantEuclidean : (polR, polR, NNI) ->
    Record(coef1 : polR, coef2 : polR, subResultant : polR)
    ++ \axiom{indiceSubResultant(P, Q, i)} returns
    ++ a subresultant \axiom{S} of degree \axiom{d}
    ++ and carries out the equality \axiom{coef1*P + coef2*Q = S_i}.

semiDegreeSubResultantEuclidean : (polR, polR, NNI) ->
    Record(coef2 : polR, subResultant : polR)
    ++ \axiom{indiceSubResultant(P, Q, i)} returns
    ++ a subresultant \axiom{S} of degree \axiom{d}
    ++ and carries out the equality \axiom{...P + coef2*Q = S_i}.
    ++ Warning. \axiom{degree(P) >= degree(Q)}.

lastSubResultant : (polR, polR) -> polR
    ++ \axiom{lastSubResultant(P, Q)} computes
    ++ the last non zero subresultant of \axiom{P} and \axiom{Q}

lastSubResultantEuclidean : (polR, polR) ->
    Record(coef1 : polR, coef2 : polR, subResultant : polR)
    ++ \axiom{lastSubResultantEuclidean(P, Q)} computes
    ++ the last non zero subresultant \axiom{S}
    ++ and carries out the equality \axiom{coef1*P + coef2*Q = S}.

semiLastSubResultantEuclidean : (polR, polR) ->
    Record(coef2 : polR, subResultant : polR)
    ++ \axiom{semiLastSubResultantEuclidean(P, Q)} computes
    ++ the last non zero subresultant \axiom{S}
    ++ and carries out the equality \axiom{...P + coef2*Q = S}.
    ++ Warning. \axiom{degree(P) >= degree(Q)}.

```

```

subResultantGcd : (polR, polR) -> polR
  ++ \axiom{subResultantGcd(P, Q)} returns the gcd
  ++ of two primitive polynomials \axiom{P} and \axiom{Q}.

subResultantGcdEuclidean : (polR, polR)
  -> Record(coef1 : polR, coef2 : polR, gcd : polR)
  ++ \axiom{subResultantGcdEuclidean(P,Q)} carries out the equality
  ++ \axiom{coef1*P + coef2*Q = +/- S_i(P,Q)}
  ++ where the degree (not the indice)
  ++ of the subresultant \axiom{S_i(P,Q)} is the smaller as possible.

semiSubResultantGcdEuclidean2 : (polR, polR)
  -> Record(coef2 : polR, gcd : polR)
  ++ \axiom{semiSubResultantGcdEuclidean2(P,Q)} carries out the equality
  ++ \axiom{...P + coef2*Q = +/- S_i(P,Q)}
  ++ where the degree (not the indice)
  ++ of the subresultant \axiom{S_i(P,Q)} is the smaller as possible.
  ++ Warning. \axiom{degree(P) >= degree(Q)}.

semiSubResultantGcdEuclidean1 : (polR, polR)->Record(coef1: polR, gcd: polR)
  ++ \axiom{semiSubResultantGcdEuclidean1(P,Q)} carries out the equality
  ++ \axiom{coef1*P + ? Q = +/- S_i(P,Q)}
  ++ where the degree (not the indice)
  ++ of the subresultant \axiom{S_i(P,Q)} is the smaller as possible.

discriminant : polR -> R
  ++ \axiom{discriminant(P, Q)} returns the discriminant
  ++ of \axiom{P} and \axiom{Q}.

discriminantEuclidean : polR ->
  Record(coef1 : polR, coef2 : polR, discriminant : R)
  ++ \axiom{discriminantEuclidean(P)} carries out the equality
  ++ \axiom{coef1 * P + coef2 * D(P) = discriminant(P)}.

semiDiscriminantEuclidean : polR ->
  Record(coef2 : polR, discriminant : R)
  ++ \axiom{discriminantEuclidean(P)} carries out the equality
  ++ \axiom{...P + coef2 * D(P) = discriminant(P)}.
  ++ Warning. \axiom{degree(P) >= degree(Q)}.

chainSubResultants : (polR, polR) -> List(polR)
  ++ \axiom{chainSubResultants(P, Q)} computes the list
  ++ of non zero subresultants of \axiom{P} and \axiom{Q}.

schema : (polR, polR) -> List(NNI)

```

```

++ \axiom{schema(P,Q)} returns the list of degrees of
++ non zero subresultants of \axiom{P} and \axiom{Q}.

if R has GcdDomain then
  resultantRedit : (polR, polR) -> R
  ++ \axiom{resultantRedit(P,Q)} returns the "reduce resultant"
  ++ of \axiom{P} and \axiom{Q}.

  resultantReditEuclidean : (polR, polR) ->
    Record(coef1 : polR, coef2 : polR, resultantRedit : R)
  ++ \axiom{resultantReditEuclidean(P,Q)} returns
  ++ the "reduce resultant" and carries out the equality
  ++ \axiom{coef1*P + coef2*Q = resultantRedit(P,Q)}.

  semiResultantReditEuclidean : (polR, polR) ->
    Record(coef2 : polR, resultantRedit : R)
  ++ \axiom{semiResultantReditEuclidean(P,Q)} returns
  ++ the "reduce resultant" and carries out the equality
  ++ \axiom{...P + coef2*Q = resultantRedit(P,Q)}.

  gcd : (polR, polR) -> polR
  ++ \axiom{gcd(P, Q)} returns the gcd of \axiom{P} and \axiom{Q}.

-- sub-routines exported for convenience -----

"*" : (R, Vector(polR)) -> Vector(polR)
++ \axiom{r * v} computes the product of \axiom{r} and \axiom{v}

"exquo" : (Vector(polR), R) -> Vector(polR)
++ \axiom{v exquo r} computes
++ the exact quotient of \axiom{v} by \axiom{r}

pseudoDivide : (polR, polR) ->
  Record(coef:R, quotient:polR, remainder:polR)
++ \axiom{pseudoDivide(P,Q)} computes the pseudoDivide
++ of \axiom{P} by \axiom{Q}.

divide : (polR, polR) -> Record(quotient : polR, remainder : polR)
++ \axiom{divide(F,G)} computes quotient and rest
++ of the exact euclidean division of \axiom{F} by \axiom{G}.

Lazard : (R, R, NNI) -> R
++ \axiom{Lazard(x, y, n)} computes \axiom{x**n/y**(n-1)}

Lazard2 : (polR, R, R, NNI) -> polR
++ \axiom{Lazard2(F, x, y, n)} computes \axiom{(x/y)**(n-1) * F}

```

```

next_sousResultant2 : (polR, polR, polR, R) -> polR
  ++ \axiom{nextsousResultant2(P, Q, Z, s)} returns
  ++ the subresultant \axiom{S_{e-1}} where
  ++ \axiom{P ~ S_d, Q = S_{d-1}, Z = S_e, s = lc(S_d)}

resultant_naif : (polR, polR) -> R
  ++ \axiom{resultantEuclidean_naif(P,Q)} returns
  ++ the resultant of \axiom{P} and \axiom{Q} computed
  ++ by means of the naive algorithm.

resultantEuclidean_naif : (polR, polR) ->
  Record(coef1 : polR, coef2 : polR, resultant : R)
  ++ \axiom{resultantEuclidean_naif(P,Q)} returns
  ++ the extended resultant of \axiom{P} and \axiom{Q} computed
  ++ by means of the naive algorithm.

semiResultantEuclidean_naif : (polR, polR) ->
  Record(coef2 : polR, resultant : R)
  ++ \axiom{resultantEuclidean_naif(P,Q)} returns
  ++ the semi-extended resultant of \axiom{P} and \axiom{Q} computed
  ++ by means of the naive algorithm.

*<package INTPAF PureAlgebraicIntegration>≡*

)abbrev package INTPAF PureAlgebraicIntegration

++ Author: Manuel Bronstein

++ Date Created: 27 May 1988

++ Date Last Updated: 24 June 1994

++ Description:

++ Integration of pure algebraic functions;

++ This package provides functions for integration, limited integration,

++ extended integration and the risch differential equation for

++ pure algebraic integrands;

PureAlgebraicIntegration(R, F, L): Exports == Implementation where

R: Join(GcdDomain, RetractableTo Integer, OrderedSet, CharacteristicZero,  
LinearlyExplicitRingOver Integer)

F: Join(FunctionSpace R, AlgebraicallyClosedField,  
TranscendentalFunctionCategory)

L: SetCategory

SY ==> Symbol

N ==> NonNegativeInteger

K ==> Kernel F

P ==> SparseMultivariatePolynomial(R, K)

UP ==> SparseUnivariatePolynomial F

RF ==> Fraction UP

UPUP==> SparseUnivariatePolynomial RF

IR ==> IntegrationResult F

IR2 ==> IntegrationResultFunctions2(curve, F)

ALG ==> AlgebraicIntegrate(R, F, UP, UPUP, curve)

```

LDALG ==> LinearOrdinaryDifferentialOperator1 curve
RDALG ==> PureAlgebraicLODE(F, UP, UPUP, curve)
LOG ==> Record(coeff:F, logand:F)
REC ==> Record(particular:U1, basis:List F)
CND ==> Record(left:UP, right:UP)
CHV ==> Record(int:UPUP, left:UP, right:UP, den:RF, deg:N)
U1 ==> Union(F, "failed")
U2 ==> Union(Record(ratpart:F, coeff:F), "failed")
U3 ==> Union(Record(mainpart:F, limitedlogs:List LOG), "failed")
FAIL==> error "failed - cannot handle that integrand"

Exports ==> with
  palgint : (F, K, K) -> IR
  ++ palgint(f, x, y) returns the integral of \spad{f(x,y)dx}
  ++ where y is an algebraic function of x.
  palgextint: (F, K, K, F) -> U2
  ++ palgextint(f, x, y, g) returns functions \spad{[h, c]} such that
  ++ \spad{dh/dx = f(x,y) - c g}, where y is an algebraic function of x;
  ++ returns "failed" if no such functions exist.
  palglimint: (F, K, K, List F) -> U3
  ++ palglimint(f, x, y, [u1,...,un]) returns functions
  ++ \spad{[h,[[ci, ui]]]} such that the ui's are among \spad{[u1,...,un]}
  ++ and \spad{d(h + sum(ci log(ui)))/dx = f(x,y)} if such functions exist,
  ++ "failed" otherwise;
  ++ y is an algebraic function of x.
  palgRDE : (F, F, F, K, K, (F, F, SY) -> U1) -> U1
  ++ palgRDE(nfp, f, g, x, y, foo) returns a function \spad{z(x,y)}
  ++ such that \spad{dz/dx + n * df/dx z(x,y) = g(x,y)} if such a z exists,
  ++ "failed" otherwise;
  ++ y is an algebraic function of x;
  ++ \spad{foo(a, b, x)} is a function that solves
  ++ \spad{du/dx + n * da/dx u(x) = u(x)}
  ++ for an unknown \spad{u(x)} not involving y.
  ++ \spad{nfp} is \spad{n * df/dx}.
  if L has LinearOrdinaryDifferentialOperatorCategory F then
    palgLDE: (L, F, K, K, SY) -> REC
    ++ palgLDE(op, g, kx, y, x) returns the solution of \spad{op f = g}.
    ++ y is an algebraic function of x.

## Chapter Q

### 18.1 package QALGSET2 QuasiAlgebraicSet2

#### 18.1.1 QuasiAlgebraicSet2 (QALGSET2)

#### Exports:

radicalSimplify

```
<package QALGSET2 QuasiAlgebraicSet2>≡
)abbrev package QALGSET2 QuasiAlgebraicSet2
++ Author: William Sit
++ Date Created: March 13, 1992
++ Date Last Updated: June 12, 1992
++ Basic Operations:
++ Related Constructors: GroebnerPackage, IdealDecompositionPackage,
++                      PolynomialIdeals
++ See Also: QuasiAlgebraicSet
++ AMS Classifications:
++ Keywords: Zariski closed sets, quasi-algebraic sets
```

```

++ References:William Sit, "An Algorithm for Parametric Linear Systems"
++           J. Sym. Comp., April, 1992
++ Description:
++ \spadtype{QuasiAlgebraicSet2} adds a function \spadfun{radicalSimplify}
++ which uses \spadtype{IdealDecompositionPackage} to simplify
++ the representation of a quasi-algebraic set. A quasi-algebraic set
++ is the intersection of a Zariski
++ closed set, defined as the common zeros of a given list of
++ polynomials (the defining polynomials for equations), and a principal
++ Zariski open set, defined as the complement of the common
++ zeros of a polynomial f (the defining polynomial for the inequation).
++ Quasi-algebraic sets are implemented in the domain
++ \spadtype{QuasiAlgebraicSet}, where two simplification routines are
++ provided:
++ \spadfun{idealSimplify} and \spadfun{simplify}.
++ The function
++ \spadfun{radicalSimplify} is added
++ for comparison study only. Because the domain
++ \spadtype{IdealDecompositionPackage} provides facilities for
++ computing with radical ideals, it is necessary to restrict
++ the ground ring to the domain \spadtype{Fraction Integer},
++ and the polynomial ring to be of type
++ \spadtype{DistributedMultivariatePolynomial}.
++ The routine \spadfun{radicalSimplify} uses these to compute groebner
++ basis of radical ideals and
++ is inefficient and restricted when compared to the
++ two in \spadtype{QuasiAlgebraicSet}.

=====
QuaternionCategoryFunctions2 examples
=====

The package QuaternionCategoryFunctions2 provides a function map
to convert an expression in Quaternion(R) to an expression in
Quaternion(S) using the function f.

q := quatern(2/11,-8,3/4,1)

      2      3
-- - 8i + - j + k
      11     4

   Type: Quaternion Fraction Integer

f(a:Fraction Integer):Complex Fraction Integer == a::Complex Fraction Integer
Function declaration f : Fraction Integer -> Complex Fraction
Integer has been added to workspace.

   Type: Void

map(f,q)
Compiling function f with type Fraction Integer -> Complex Fraction
Integer

      2      3
-- - 8i + - j + k
      11     4

   Type: Quaternion Complex Fraction Integer

++ Author: P. Gianni
++ Date created: ??
++ Date last updated: December 1993
++ Keywords: factorization, hensel, rational number
++ Description:
++ Factorization of extended polynomials with rational coefficients.
++ This package implements factorization of extended polynomials
++ whose coefficients are rational numbers. It does this by taking the
++ lcm of the coefficients of the polynomial and creating a polynomial
++ with integer coefficients. The algorithm in
++ \spadtype{GaloisGroupFactorizer} is then
++ used to factor the integer polynomial. The result is normalized
++ with respect to the original lcm of the denominators.

=====

RationalFunctionSum examples

=====

There are 4 different forms of the sum operator in this domain.  
They are variations of the types of the input

`sum(i::Polynomial(Integer),variable(i=1..n))`

$$\frac{6i^2 - 6i + 1}{12}$$

`sum(i::Fraction(Polynomial(Integer)),i::Symbol)`

$$\frac{6i^2 - 6i + 1}{12}$$

`sum(i,i=1..n)`

$$\frac{n^2 + n}{2}$$

`sum(i::Fraction(Polynomial(Integer)),i=1..n)`

$$\frac{n^2 + n}{2}$$

We can compute the sum form on part at a time to see what happens.  
First, we make a `SegmentBinding(Polynomial(Integer))`:

`s:=i=1..n`

`i= 1..n`

We pick out the upper and lower bounds of the segment:

```
hiseg:=high(segment(s))
```

```
n
```

```
loseg:=low(segment(s))
```

```
1
```

We pick out the variable from the segment:

```
v:=variable s
```

```
i
```

We create a polynomial we wish to sum:

```
p:=i::Polynomial(Integer)
```

```
i
```

And we create the sum for that polynomial:

```
f:=sum(p,v)
```

$$\frac{6i^2 - 6i + 1}{12}$$

The new evaluate it at the upper endpoint:

```
t1:=eval(f,v,(1+hiseg))
```

$$\frac{6n^2 + 6n + 1}{12}$$

And the lower endpoint:

```
t2:=eval(f,v,loseg)
```

$$\frac{1}{12}$$

And we take the difference of the endpoints:

```
t1-t2
```

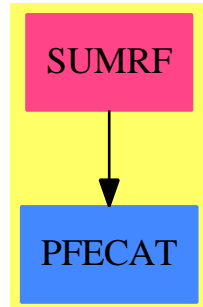

$$\frac{n^2 + n}{2}$$

## 19.18 package RINTERP RationalInterpolation

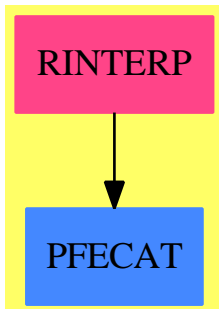

### 19.18.1 Introduction

This file contains a crude naïve implementation of rational interpolation, where the coefficients of the rational function are in any given field.

### 19.18.2 Questions and Outlook

- Maybe this file should be joined with `pinterp.spad`, where polynomial Lagrange interpolation is implemented. I have a second version that parallels the structure of `pinterp.spad` closely.
- There are probably better ways to implement rational interpolation. Maybe <http://www.cs.ucsb.edu/~omer/personal/abstracts/rational.html> contains something useful, but I don't know.
- Comments welcome!

### 19.18.3 RationalInterpolation (RINTERP)

#### Exports:

`interpolate`

```

<package RINTERP RationalInterpolation>≡
)abbrev package RINTERP RationalInterpolation
++ Description:
++ This package exports rational interpolation algorithms

RationalInterpolation(xx,F): Exports == Implementation where
  xx: Symbol
  F: Field
  Exports == with
  
```

```
interpolate: (List F, List F, NonNegativeInteger,
              NonNegativeInteger) -> Fraction Polynomial F
```

The implementation sets up a system of linear equations and solves it.

```
<package RINTERP RationalInterpolation>+≡
  Implementation == add
    interpolate(xlist, ylist, m, k) ==
```

First we check whether we have the right number of points and values. Clearly the number of points and the number of values must be identical. Note that we want to determine the numerator and denominator polynomials only up to a factor. Thus, we want to determine  $m + k + 1$  coefficients, where  $m$  is the degree of the polynomial in the numerator and  $k$  is the degree of the polynomial in the denominator.

In fact, we could also leave – for example –  $k$  unspecified and determine it as  $k = \#xlist - m - 1$ : I don't know whether this would be better.

```
<package RINTERP RationalInterpolation>+≡
  #xlist ^= #ylist =>
    error "Different number of points and values."
  #xlist ^= m+k+1 =>
    error "wrong number of points"
```

The next step is to set up the matrix. Suppose that our numerator polynomial is  $p(x) = a_0 + a_1x + \dots + a_mx^m$  and that our denominator polynomial is  $q(x) = b_0 + b_1x + \dots + b_kx^k$ . Then we have the following equations, writing  $n$  for  $m + k + 1$ :

$$\begin{aligned} p(x_1) - y_1q(x_1) &= a_0 + a_1x_1 + \dots + a_mx_1^m - y_1(b_0 + b_1x_1 + \dots + b_kx_1^k) = 0 \\ p(x_2) - y_2q(x_2) &= a_0 + a_1x_2 + \dots + a_mx_2^m - y_2(b_0 + b_1x_2 + \dots + b_kx_2^k) = 0 \\ &\vdots \\ p(x_n) - y_nq(x_n) &= a_0 + a_1x_n + \dots + a_mx_n^m - y_n(b_0 + b_1x_n + \dots + b_kx_n^k) = 0 \end{aligned}$$

This can be written as

$$\begin{bmatrix} 1 & x_1 & \dots & x_1^m & -y_1 & -y_1x_1 & \dots & -y_1x_1^k \\ 1 & x_2 & \dots & x_2^m & -y_2 & -y_2x_2 & \dots & -y_2x_2^k \\ & & & \vdots & & & & \\ 1 & x_n & \dots & x_n^m & -y_n & -y_nx_n & \dots & -y_nx_n^k \end{bmatrix} \begin{bmatrix} a_0 \\ a_1 \\ \vdots \\ a_m \\ b_0 \\ b_1 \\ \vdots \\ b_k \end{bmatrix} = \mathbf{0}$$

We generate this matrix columnwise:

```
(package RINTERP RationalInterpolation)+≡
tempvec: List F := [1 for i in 1..(m+k+1)]

collist: List List F := cons(tempvec,
                             [(tempvec := [tempvec.i * xlist.i _
   for i in 1..(m+k+1)]) _
                             for j in 1..max(m,k)])

collist := append([collist.j for j in 1..(m+1)], _
                  [[- collist.j.i * ylist.i for i in 1..(m+k+1)] _
                   for j in 1..(k+1)])
```

Now we can solve the system:

```
(package RINTERP RationalInterpolation)+≡
res: List Vector F := nullSpace((transpose matrix collist) _
                                ::Matrix F)
```

Note that it may happen that the system has several solutions. In this case, some of the data points may not be interpolated correctly. However, the solution is often still useful, thus we do not signal an error.

```
(package RINTERP RationalInterpolation)+≡
if #res~1 then output("Warning: unattainable points!" _
                      ::OutputForm)$OutputPackage
```

In this situation, all the solutions will be equivalent, thus we can always simply take the first one:

```
<package RINTERP RationalInterpolation>+≡
      reslist: List List Polynomial F := _
          [[(res.1).(i+1)*(xx::Polynomial F)**i for i in 0..m], _
           [(res.1).(i+m+2)*(xx::Polynomial F)**i for i in 0..k]]
```

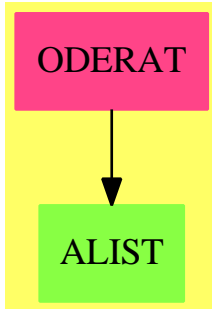

Finally, we generate the rational function:

```
<package RINTERP RationalInterpolation>+≡
      reduce((_+),reslist.1)/reduce((_+),reslist.2)

<RINTERP.dotabb>≡
  "RINTERP" [color="#FF4488",href="bookvol10.4.pdf#nameddest=RINTERP"]
  "PFECAT"  [color="#4488FF",href="bookvol10.2.pdf#nameddest=PFECAT"]
  "RINTERP" -> "PFECAT"
```

rur: (LP,Boolean) -> List RUR
  ++ \spad{rur(lp,univ?) } returns a rational univariate representation
  ++ of \spad{lp}. This assumes that \spad{lp} defines a regular
  ++ triangular \spad{ts} whose associated variety is zero-dimensional
  ++ over \spad{R}. \spad{rur(lp,univ?) } returns a list of items
  ++ \spad{[u,lc]} where \spad{u} is an irreducible univariate polynomial
  ++ and each \spad{c} in \spad{lc} involves two variables: one from \spad{ls},
  ++ called the coordinate of \spad{c}, and an extra variable which
  ++ represents any root of \spad{u}. Every root of \spad{u} leads to
  ++ a tuple of values for the coordinates of \spad{lc}. Moreover,
  ++ a point \spad{x} belongs to the variety associated with \spad{lp} iff
  ++ there exists an item \spad{[u,lc]} in \spad{rur(lp,univ?) } and
  ++ a root \spad{r} of \spad{u} such that \spad{x} is given by the
  ++ tuple of values for the coordinates of \spad{lc} evaluated at \spad{r}.
  ++ If \spad{univ?} is \spad{true} then each polynomial \spad{c}
  ++ will have a constant leading coefficient w.r.t. its coordinate.
  ++ See the example which illustrates the \spadtype{ZeroDimensionalSolvePackage}
  ++ package constructor.
rur: (LP) -> List RUR
  ++ \spad{rur(lp)} returns the same as \spad{rur(lp,true)}
rur: (LP,Boolean,Boolean) -> List RUR
  ++ \spad{rur(lp,univ?,check?) } returns the same as \spad{rur(lp,true)}.
  ++ Moreover, if \spad{check?} is \spad{true} then the result is checked.

## 19.23 package POLUTIL RealPolynomialUtilitiesPackage

This file describes the Real Closure 1.0 package which consists of different packages, categories and domains :

The package RealPolynomialUtilitiesPackage which receives a field and a univariate polynomial domain with coefficients in the field. It computes some simple functions such as Sturm and Sylvester sequences.

The category RealRootCharacterizationCategory provides abstract functionalities to work with "real roots" of univariate polynomials. These resemble variables with some functionalities needed to compute important operations.

RealClosedField is a category which provides common operations available over real closed fields. These include finding all the roots of univariate polynomial, taking square roots, ...

### CAVEATS

Since real algebraic expressions are stored as depending on "real roots" which are managed like variables, there is an ordering on these. This ordering is dynamical in the sense that any new algebraic takes precedence over older ones. In particular every creation function raises a new "real root". This has the effect that when you type something like  $\sqrt{2} + \sqrt{2}$  you have two new variables which happen to be equal. To avoid this name the expression such as in  $s2 := \sqrt{2} ; s2 + s2$

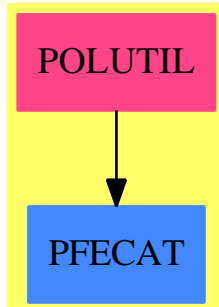

Also note that computing times depend strongly on the ordering you implicitly provide. Please provide algebraics in the order which most natural to you.

### LIMITATIONS

The file reclos.input shows some basic use of the package. This package uses algorithms which are published in [1] and [2] which are based on field arithmetics, in particular for polynomial gcd related algorithms. This can be quite slow for high degree polynomials and subresultants methods usually work best. Beta versions of the package try to use these techniques in a better way and work significantly faster. These are mostly based on unpublished algorithms and cannot be distributed. Please contact the author if you have a particular problem to solve or want to use these versions.

Be aware that approximations behave as post-processing and that all computations are done exactly. They can thus be quite time consuming when depending on several "real roots".

```

```

Exports == with

```

```

evalRec: (BasicOperator, Symbol, F, F, F, List F) -> F
++ \spad{evalRec(u, dummy, n, n0, eq, values)} creates an expression that
++ stands for u(n0), where u(n) is given by the equation eq. However, for
++ technical reasons the variable n has to be replaced by a dummy
++ variable dummy in eq. The argument values specifies the initial values
++ of the recurrence u(0), u(1),...
++ For the moment we don't allow recursions that contain u inside of
++ another operator.

```

```

evalADE: (BasicOperator, Symbol, F, F, F, List F) -> F

```

```

++ \spad{evalADE(f, dummy, x, n, eq, values)} creates an expression that
++ stands for the coefficient of  $x^n$  in the Taylor expansion of  $f(x)$ ,
++ where  $f(x)$  is given by the functional equation eq. However, for
++ technical reasons the variable  $x$  has to be replaced by a dummy
++ variable dummy in eq. The argument values specifies the first few
++ Taylor coefficients.

getEq: F -> F
++ \spad{getEq f} returns the defining equation, if f represents the
++ coefficient of an ADE or a recurrence.

getOp: F -> BasicOperator
++ \spad{getOp f}, if f represents the coefficient of a recurrence or
++ ADE, returns the operator representing the solution

    Record(max: Union(Integer, "failed"),
           ord: Union(Integer, "failed"),
           ker: Kernel F)

Implementation == add
<implementation: RecurrenceOperator>

```

### 19.28.2 Defining new operators

We define two new operators, one for recurrences, the other for functional equations. The operators for recurrences represents the  $n^{\text{th}}$  term of the corresponding sequence, the other the coefficient of  $x^n$  in the Taylor series expansion.

```

<implementation: RecurrenceOperator>≡
  oprecur := operator("rootOfRec"::Symbol)$BasicOperator

  opADE := operator("rootOfADE"::Symbol)$BasicOperator

  setProperty(oprecur, "%dummyVar", 2 pretend None)
  setProperty(opADE, "%dummyVar", 2 pretend None)

```

Setting these properties implies that the second and third arguments of `oprecur` are dummy variables and affects `tower$ES`: the second argument will not appear in `tower$ES`, if it does not appear in any argument but the first and second. The third argument will not appear in `tower$ES`, if it does not appear in any other argument. (`%defsum` is a good example)

The arguments of the two operators are as follows:

1. `eq`, i.e. the vanishing expression

```
<implementation: RecurrenceOperator>+≡
eqAsF: List F -> F
eqAsF l == l.1
```

2. `dummy`, a dummy variable to make substitutions possible

```
<implementation: RecurrenceOperator>+≡
dummy: List F -> Symbol
dummy l == retract(l.2)@Symbol

dummyAsF: List F -> F
dummyAsF l == l.2
```

3. the variable for display

```
<implementation: RecurrenceOperator>+≡
displayVariable: List F -> F
displayVariable l == l.3
```

4. `operatorName(argument)`

```
<implementation: RecurrenceOperator>+≡
operatorName: List F -> BasicOperator
operatorName l == operator(kernels(l.4).1)

operatorNameAsF: List F -> F
operatorNameAsF l == l.4

operatorArgument: List F -> F
operatorArgument l == argument(kernels(l.4).1).1
```

Concerning `rootOfADE`, note that although we have `arg` as argument of the operator, it is intended to indicate the coefficient, not the argument of the power series.

5. `values` in reversed order.

- `rootOfRec`: maybe `values` should be preceded by the index of the first given value. Currently, the last value is interpreted as  $f(0)$ .
- `rootOfADE`: values are the first few coefficients of the power series expansion in order.

```

<implementation: RecurrenceOperator> +=
  initialValues: List F -> List F
  initialValues l == rest(l, 4)

```

### 19.28.3 Recurrences

#### Extracting some information from the recurrence

We need to find out whether we can determine the next term of the sequence, and how many initial values are necessary.

```

<implementation: RecurrenceOperator> +=
  if R has Ring then
    getShiftRec(op: BasicOperator, f: Kernel F, n: Symbol)
      : Union(Integer, "failed") ==
        a := argument f
        if every?(z +-> freeOf?(z, n::F), a) then return 0

        if #a ~= 1 then error "RECOP: operator should have only one argument"

        p := univariate(a.1, retract(n::F)@Kernel(F))
        if denominator p ~= 1 then return "failed"

        num := numer p

        if degree num = 1 and coefficient(num, 1) = 1
          and every?(z +-> freeOf?(z, n::F), coefficients num)
          then return retractIfCan(coefficient(num, 0))
          else return "failed"

-- if the recurrence is of the form
-- $p(n, f(n+m-o), f(n+m-o+1), \dots, f(n+m)) = 0$
-- in which case shiftInfoRec returns [m, o, f(n+m)].

    shiftInfoRec(op: BasicOperator, argsym: Symbol, eq: F):
      Record(max: Union(Integer, "failed"),
        ord: Union(Integer, "failed"),
        ker: Kernel F) ==

-- ord and ker are valid only if all shifts are Integers
-- ker is the kernel of the maximal shift.
    maxShift: Integer
    minShift: Integer
    nextKernel: Kernel F

-- We consider only those kernels that have op as operator. If there is none,
-- we raise an error. For the moment we don't allow recursions that contain op
-- inside of another operator.

    error? := true

```

```

for f in kernels eq repeat
  if is?(f, op) then
    shift := getShiftRec(op, f, argsym)
    if error? then
      error? := false
      nextKernel := f
      if shift case Integer then
        maxShift := shift
        minShift := shift
      else return ["failed", "failed", nextKernel]
    else
      if shift case Integer then
        if maxShift < shift then
          maxShift := shift
          nextKernel := f
        if minShift > shift then
          minShift := shift
        else return ["failed", "failed", nextKernel]

if error? then error "evalRec: equation does not contain operator"

[maxShift, maxShift - minShift, nextKernel]

```

**Evaluating a recurrence**

```

<implementation: RecurrenceOperator> +=
  evalRec(op, argsym, argdisp, arg, eq, values) ==
    if ((n := retractIfCan(arg)@Union(Integer, "failed")) case "failed")
      or (n < 0)
    then
      shiftInfo := shiftInfoRec(op, argsym, eq)

      if (shiftInfo.ord case "failed") or ((shiftInfo.ord)::Integer > 0)
      then
        kernel(oprecur,
          append([eq, argsym::F, argdisp, op(arg)], values))
      else
        p := univariate(eq, shiftInfo.ker)
        num := numer p

-- If the degree is 1, we can return the function explicitly.

    if degree num = 1 then
      eval(-coefficient(num, 0)/coefficient(num, 1), argsym::F,
        arg::F-(shiftInfo.max)::Integer::F)
    else
      kernel(oprecur,
        append([eq, argsym::F, argdisp, op(arg)], values))
  else
    len: Integer := #values
    if n < len
    then values.(len-n)
    else
      shiftInfo := shiftInfoRec(op, argsym, eq)

      if shiftInfo.max case Integer then
        p := univariate(eq, shiftInfo.ker)

        num := numer p

      if degree num = 1 then

        next := -coefficient(num, 0)/coefficient(num, 1)
        nextval := eval(next, argsym::F,
          (len-(shiftInfo.max)::Integer)::F)
        newval := eval(nextval, op,
          z+>evalRec(op, argsym, argdisp, z, eq, values))
        evalRec(op, argsym, argdisp, arg, eq, cons(newval, values))
      else

```

```

        kernel(oprecur,
              append([eq, argsym::F, argdisp, op(arg)], values))

    else
        kernel(oprecur,
              append([eq, argsym::F, argdisp, op(arg)], values))

numberOfValuesNeeded(numberOfValues: Integer,
                    op: BasicOperator,
                    argsym: Symbol, eq: F): Integer ==
    order := shiftInfoRec(op, argsym, eq).ord
    if order case Integer
    then min(numberOfValues, retract(order)@Integer)
    else numberOfValues

else
    evalRec(op, argsym, argdisp, arg, eq, values) ==
        kernel(oprecur,
              append([eq, argsym::F, argdisp, op(arg)], values))

numberOfValuesNeeded(numberOfValues: Integer,
                    op: BasicOperator, argsym: Symbol, eq: F): Integer ==
    numberOfValues

```

### Setting the evaluation property of oprecur

irecur is just a wrapper that allows us to write a recurrence relation as an operator.

```

<implementation: RecurrenceOperator>+≡
    irecur: List F -> F
    irecur l ==
        evalRec(operatorName l,
              dummy l, displayVariable l,
              operatorArgument l, eqAsF l, initialValues l)

evaluate(oprecur, irecur)$BasicOperatorFunctions1(F)

```

### Displaying a recurrence relation

```

<implementation: RecurrenceOperator>+≡
  ddrec: List F -> OutputForm
  ddrec l ==
    op := operatorName l
    values := reverse l
    eq := eqAsF l

    numberOfValues := numberOfValuesNeeded(#values-4, op, dummy l, eq)

    vals: List OutputForm
    := cons(eval(eq, dummyAsF l, displayVariable l)::OutputForm = _
            0::OutputForm,
            [elt(op::OutputForm, [(i-1)::OutputForm]) = _
            (values.i)::OutputForm
            for i in 1..numberOfValues])

    bracket(hconcat([(operatorNameAsF l)::OutputForm,
                    ": ",
                    commaSeparate vals])))

setProperty(oprecur, "%specialDisp",
            ddrec@(List F -> OutputForm) pretend None)

```

## 19.28.4 Functional Equations

### Determining the number of initial values for ADE's

We use Joris van der Hoeven's instructions for ADE's. Given  $Q = p(f, f', \dots, f^{(r)})$  we first need to differentiate  $Q$  with respect to  $f^{(i)}$  for  $i \in \{0, 1, \dots, r\}$ , plug in the given truncated power series solution and determine the valuation.

```

<NOTYET implementation: RecurrenceOperator>≡
  getValuation(op, argsym, eq, maxorder, values): Integer ==
    max: Integer := -1;
    ker: Kernel F
    for i in 0..maxorder repeat
      ker := D(op(argsym), argsym, i)::Kernel F
      pol := univariate(eq, ker)
      dif := D pol
      ground numer(dif.D(op(argsym), argsym, i))

```

**Extracting some information from the functional equation**

`getOrder` returns the maximum derivative of `op` occurring in `f`.

```
<implementation: RecurrenceOperator>+≡
  getOrder(op: BasicOperator, f: Kernel F): NonNegativeInteger ==
    res: NonNegativeInteger := 0
    g := f
    while is?(g, %diff) repeat
      g := kernels(argument(g).1).1
      res := res+1

    if is?(g, op) then res else 0
```

**Extracting a coefficient given a functional equation**

```

<implementation: RecurrenceOperator>+≡
  evalADE(op, argsym, argdisp, arg, eq, values) ==

<package RSDCMPK RegularSetDecompositionPackage>≡
)abbrev package RSDCMPK RegularSetDecompositionPackage
++ Author: Marc Moreno Maza
++ Date Created: 09/16/1998
++ Date Last Updated: 12/16/1998
++ Basic Functions:
++ Related Constructors:
++ Also See:
++ AMS Classifications:
++ Keywords:
++ References :
++ [1] M. MORENO MAZA "A new algorithm for computing triangular
++      decomposition of algebraic varieties" NAG Tech. Rep. 4/98.
++ Description:
++ A package providing a new algorithm for solving polynomial systems
++ by means of regular chains. Two ways of solving are proposed:
++ in the sense of Zariski closure (like in Kalkbrener's algorithm)
++ or in the sense of the regular zeros (like in Wu, Wang or Lazard
++ methods). This algorithm is valid for nay type
++ of regular set. It does not care about the way a polynomial is
++ added in an regular set, or how two quasi-components are compared
++ (by an inclusion-test), or how the invertibility test is made in
++ the tower of simple extensions associated with a regular set.
++ These operations are realized respectively by the domain \spad{TS}
  
```

```

++ and the packages
++ \axiomType{QCMACK}(R,E,V,P,TS) and \axiomType{RSETGCD}(R,E,V,P,TS).
++ The same way it does not care about the way univariate polynomial
++ gcd (with coefficients in the tower of simple extensions associated
++ with a regular set) are computed. The only requirement is that these
++ gcd need to have invertible initials (normalized or not).
++ WARNING. There is no need for a user to call directly any operation
++ of this package since they can be accessed by the domain \axiom{TS}.
++ Thus, the operations of this package are not documented.

```

## 19.35 package REPSQ RepeatedSquaring

This code computes  $x^n$  by repeated squaring. It takes advantage of the law of exponents so that if  $n = a * b$  then

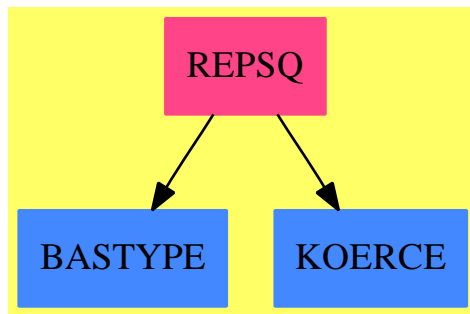

$$x^n = x^a x^b$$

It also takes advantage of the fact that  $n$  has a binary representation so that a one-bit right-shift of a number divides it by 2. Thus we get three cases:

$$\begin{aligned} n = 1 &\rightarrow x^1 \\ n \text{ odd} &\rightarrow \text{repeatedsquare}(x * x, n/2) * x \\ n \text{ even} &\rightarrow \text{repeatedsquare}(x * x, n/2) \end{aligned}$$

Since each recursive call divides  $n$  by 2 the algorithm is  $O(\log(n))$ .

++ Description:
++ RepresentationPackage1 provides functions for representation theory
++ for finite groups and algebras.
++ The package creates permutation representations and uses tensor products
++ and its symmetric and antisymmetric components to create new
++ representations of larger degree from given ones.
  
```

```

++ Note that instead of having parameters from \spadtype{Permutation}
++ this package allows list notation of permutations as well:
++ e.g. \spad{[1,4,3,2]} denotes permutes 2 and 4 and fixes 1 and 3.

if R has commutative("*") then
  antisymmetricTensors : (M R,PI) -> M R
  ++ antisymmetricTensors(a,n) applies to the square matrix
  ++ a the irreducible, polynomial representation of the
  ++ general linear group GLm, where m is the number of
  ++ rows of a, which corresponds to the partition
  ++ (1,1,...,1,0,0,...,0) of n.
  ++ Error: if n is greater than m.
  ++ Note that this corresponds to the symmetrization of the
  ++ representation with the sign representation of the symmetric group
  ++ Sn. The carrier spaces of the representation are the antisymmetric
  ++ tensors of the n-fold tensor product.
if R has commutative("*") then
  antisymmetricTensors : (L M R, PI) -> L M R
  ++ antisymmetricTensors(la,n) applies to each
  ++ m-by-m square matrix in
  ++ the list la the irreducible, polynomial representation
  ++ of the general linear group GLm
  ++ which corresponds
  ++ to the partition (1,1,...,1,0,0,...,0) of n.
  ++ Error: if n is greater than m.
  ++ Note that this corresponds to the symmetrization of the
  ++ representation with the sign representation of the symmetric group
  ++ Sn. The carrier spaces of the representation are the antisymmetric

```

```

    ++ tensors of the n-fold tensor product.
createGenericMatrix : NNI -> M P R
    ++ createGenericMatrix(m) creates a square matrix of dimension k
    ++ whose entry at the i-th row and j-th column is the
    ++ indeterminate x[i,j] (double subscripted).
symmetricTensors : (M R, PI) -> M R
    ++ symmetricTensors(a,n) applies to the m-by-m
    ++ square matrix a the
    ++ irreducible, polynomial representation of the general linear
    ++ group GLm
    ++ which corresponds to the partition (n,0,...,0) of n.
    ++ Error: if a is not a square matrix.
    ++ Note that this corresponds to the symmetrization of the
    ++ representation with the trivial representation of the symmetric
    ++ group Sn.
    ++ The carrier spaces of the representation are the symmetric
    ++ tensors of the n-fold tensor product.
symmetricTensors : (L M R, PI) -> L M R
    ++ symmetricTensors(la,n) applies to each m-by-m square matrix in the
    ++ list la the irreducible, polynomial representation
    ++ of the general linear group GLm
    ++ which corresponds
    ++ to the partition (n,0,...,0) of n.
    ++ Error: if the matrices in la are not square matrices.
    ++ Note that this corresponds to the symmetrization of the
    ++ representation with the trivial representation of the symmetric
    ++ group Sn.
    ++ The carrier spaces of the representation are the symmetric
    ++ tensors of the n-fold tensor product.
tensorProduct : (M R, M R) -> M R
    ++ tensorProduct(a,b) calculates the Kronecker product
    ++ of the matrices a and b.
    ++ Note that if each matrix corresponds to a group representation
    ++ (repr. of generators) of one group, then these matrices
    ++ correspond to the tensor product of the two representations.
tensorProduct : (L M R, L M R) -> L M R
    ++ tensorProduct([a1,...,ak],[b1,...,bk]) calculates the list of
    ++ Kronecker products of the matrices ai and bi
    ++ for {1 <= i <= k}.
    ++ Note that if each list of matrices corresponds to a group
    ++ representation (repr. of generators) of one group, then these
    ++ matrices correspond to the tensor product of the two representations.
tensorProduct : M R -> M R
    ++ tensorProduct(a) calculates the Kronecker product
    ++ of the matrix a with itself.
tensorProduct : L M R -> L M R

```

```

++ tensorProduct([a1,...ak]) calculates the list of
++ Kronecker products of each matrix ai with itself
++ for {1 <= i <= k}.
++ Note that if the list of matrices corresponds to a group
++ representation (repr. of generators) of one group, then these
++ matrices correspond to the tensor product of the representation
++ with itself.
permutationRepresentation : (PERM I, I) -> M I
++ permutationRepresentation(pi,n) returns the matrix
++ (deltai,pi(i)) (Kronecker delta) for a permutation
++ pi of {1,2,...,n}.
permutationRepresentation : L I -> M I
++ permutationRepresentation(pi,n) returns the matrix
++ (deltai,pi(i)) (Kronecker delta) if the permutation
++ pi is in list notation and permutes {1,2,...,n}.
permutationRepresentation : (L PERM I, I) -> L M I
++ permutationRepresentation([pi1,...,pik],n) returns the list
++ of matrices [(deltai,pi1(i)),...,(deltai,pik(i))]
++ (Kronecker delta) for the permutations pi1,...,pik
++ of {1,2,...,n}.
permutationRepresentation : L L I -> L M I
++ permutationRepresentation([pi1,...,pik],n) returns the list
++ of matrices [(deltai,pi1(i)),...,(deltai,pik(i))]
++ if the permutations pi1,...,pik are in
++ list notation and are permuting {1,2,...,n}.

++   their Realization in the Computer Algebra System Scratchpad,
++   Bayreuther Mathematische Schriften, Heft 33, 1990, 1-23.
++ Description:
++ RepresentationPackage2 provides functions for working with
++ modular representations of finite groups and algebra.
++ The routines in this package are created, using ideas of R. Parker,
++ (the meat-Axe) to get smaller representations from bigger ones,
++ i.e. finding sub- and factormodules, or to show, that such the
  
```

```

++ representations are irreducible.
++ Note that most functions are randomized functions of Las Vegas type
++ i.e. every answer is correct, but with small probability
++ the algorithm fails to get an answer.

public ==> with

completeEchelonBasis : V V R -> M R
++ completeEchelonBasis(lv) completes the basis lv assumed
++ to be in echelon form of a subspace of R**n (n the length
++ of all the vectors in lv with unit vectors to a basis of
++ R**n. It is assumed that the argument is not an empty
++ vector and that it is not the basis of the 0-subspace.
++ Note that the rows of the result correspond to the vectors
++ of the basis.
createRandomElement : (L M R, M R) -> M R
++ createRandomElement(aG,x) creates a random element of the group
++ algebra generated by aG.
-- randomWord : (L L I, L M) -> M R
--++ You can create your own 'random' matrix with "randomWord(lli, lm)".
--++ Each li in lli determines a product of matrices, the entries in li
--++ determine which matrix from lm is chosen. Finally we sum over all
--++ products. The result "sm" can be used to call split with (e.g.)
--++ second parameter "first nullSpace sm"
if R has EuclideanDomain then -- using rowEchelon
cyclicSubmodule : (L M R, V R) -> V V R
++ cyclicSubmodule(lm,v) generates a basis as follows.
++ It is assumed that the size n of the vector equals the number
++ of rows and columns of the matrices. Then the matrices generate
++ a subalgebra, say \spad{A}, of the algebra of all square matrices of
++ dimension n. V R is an \spad{A}-module in the natural way.
++ cyclicSubmodule(lm,v) generates the R-Basis of Av as

```

```

++ described in section 6 of R. A. Parker's "The Meat-Axe".
++ Note that in contrast to the description in "The Meat-Axe" and to
++ standardBasisOfCyclicSubmodule the result is in echelon form.
standardBasisOfCyclicSubmodule : (L M R, V R) -> M R
++ standardBasisOfCyclicSubmodule(lm,v) returns a matrix as follows.
++ It is assumed that the size n of the vector equals the number
++ of rows and columns of the matrices. Then the matrices generate
++ a subalgebra, say \spad{A},
++ of the algebra of all square matrices of
++ dimension n. V R is an \spad{A}-module in the natural way.
++ standardBasisOfCyclicSubmodule(lm,v) calculates a matrix whose
++ non-zero column vectors are the R-Basis of Av achieved
++ in the way as described in section 6
++ of R. A. Parker's "The Meat-Axe".
++ Note that in contrast to cyclicSubmodule, the result is not
++ in echelon form.
if R has Field then -- only because of inverse in SM
areEquivalent? : (L M R, L M R, B, I) -> M R
++ areEquivalent?(aG0,aG1,randomelements,numberOfTries) tests
++ whether the two lists of matrices, all assumed of same
++ square shape, can be simultaneously conjugated by a non-singular
++ matrix. If these matrices represent the same group generators,
++ the representations are equivalent.
++ The algorithm tries
++ numberOfTries times to create elements in the
++ generated algebras in the same fashion. If their ranks differ,
++ they are not equivalent. If an
++ isomorphism is assumed, then
++ the kernel of an element of the first algebra
++ is mapped to the kernel of the corresponding element in the
++ second algebra. Now consider the one-dimensional ones.
++ If they generate the whole space (e.g. irreducibility !)
++ we use standardBasisOfCyclicSubmodule to create the
++ only possible transition matrix. The method checks whether the
++ matrix conjugates all corresponding matrices from aGi.
++ The way to choose the singular matrices is as in meatAxe.
++ If the two representations are equivalent, this routine
++ returns the transformation matrix TM with
++ aG0.i * TM = TM * aG1.i for all i. If the representations
++ are not equivalent, a small 0-matrix is returned.
++ Note that the case
++ with different sets of group generators cannot be handled.
areEquivalent? : (L M R, L M R) -> M R
++ areEquivalent?(aG0,aG1) calls areEquivalent?(aG0,aG1,true,25).
++ Note that the choice of 25 was rather arbitrary.
areEquivalent? : (L M R, L M R, I) -> M R

```

```

++ areEquivalent?(aG0,aG1,numberOfTries) calls
++ areEquivalent?(aG0,aG1,true,25).
++ Note that the choice of 25 was rather arbitrary.
isAbsolutelyIrreducible? : (L M R, I) -> B
++ isAbsolutelyIrreducible?(aG, numberOfTries) uses
++ Norton's irreducibility test to check for absolute
++ irreducibility, assuming if a one-dimensional kernel is found.
++ As no field extension changes create "new" elements
++ in a one-dimensional space, the criterium stays true
++ for every extension. The method looks for one-dimensionals only
++ by creating random elements (no fingerprints) since
++ a run of meatAxe would have proved absolute irreducibility
++ anyway.
isAbsolutelyIrreducible? : L M R -> B
++ isAbsolutelyIrreducible?(aG) calls
++ isAbsolutelyIrreducible?(aG,25).
++ Note that the choice of 25 was rather arbitrary.
split : (L M R, V R) -> L L M R
++ split(aG, vector) returns a subalgebra \spad{A} of all
++ square matrix of dimension n as a list of list of matrices,
++ generated by the list of matrices aG, where n denotes both
++ the size of vector as well as the dimension of each of the
++ square matrices.
++ V R is an A-module in the natural way.
++ split(aG, vector) then checks whether the cyclic submodule
++ generated by vector is a proper submodule of V R.
++ If successful, it returns a two-element list, which contains
++ first the list of the representations of the submodule,
++ then the list of the representations of the factor module.
++ If the vector generates the whole module, a one-element list
++ of the old representation is given.
++ Note that a later version this should call the other split.
split: (L M R, V V R) -> L L M R
++ split(aG,submodule) uses a proper submodule of R**n
++ to create the representations of the submodule and of
++ the factor module.
if (R has Finite) and (R has Field) then
meatAxe : (L M R, B, I, I) -> L L M R
++ meatAxe(aG,randomElements,numberOfTries, maxTests) returns
++ a 2-list of representations as follows.
++ All matrices of argument aG are assumed to be square
++ and of equal size.
++ Then \spad{aG} generates a subalgebra, say \spad{A}, of the algebra
++ of all square matrices of dimension n. V R is an A-module
++ in the usual way.
++ meatAxe(aG,numberOfTries, maxTests) creates at most

```

```

++ numberOfTries random elements of the algebra, tests
++ them for singularity. If singular, it tries at most maxTests
++ elements of its kernel to generate a proper submodule.
++ If successful, a 2-list is returned: first, a list
++ containing first the list of the
++ representations of the submodule, then a list of the
++ representations of the factor module.
++ Otherwise, if we know that all the kernel is already
++ scanned, Norton's irreducibility test can be used either
++ to prove irreducibility or to find the splitting.
++ If randomElements is false, the first 6 tries
++ use Parker's fingerprints.
meatAxe : L M R -> L L M R
++ meatAxe(aG) calls meatAxe(aG,false,25,7) returns
++ a 2-list of representations as follows.
++ All matrices of argument \spad{aG} are assumed to be square
++ and of
++ equal size. Then \spad{aG} generates a subalgebra,
++ say \spad{A}, of the algebra
++ of all square matrices of dimension n. V R is an A-module
++ in the usual way.
++ meatAxe(aG) creates at most 25 random elements
++ of the algebra, tests
++ them for singularity. If singular, it tries at most 7
++ elements of its kernel to generate a proper submodule.
++ If successful a list which contains first the list of the
++ representations of the submodule, then a list of the
++ representations of the factor module is returned.
++ Otherwise, if we know that all the kernel is already
++ scanned, Norton's irreducibility test can be used either
++ to prove irreducibility or to find the splitting.
++ Notes: the first 6 tries use Parker's fingerprints.
++ Also, 7 covers the case of three-dimensional kernels over
++ the field with 2 elements.
meatAxe: (L M R, B) -> L L M R
++ meatAxe(aG, randomElements) calls meatAxe(aG,false,6,7),
++ only using Parker's fingerprints, if randomElemnts is false.
++ If it is true, it calls meatAxe(aG,true,25,7),
++ only using random elements.
++ Note that the choice of 25 was rather arbitrary.
++ Also, 7 covers the case of three-dimensional kernels over the field
++ with 2 elements.
meatAxe : (L M R, PI) -> L L M R
++ meatAxe(aG, numberOfTries) calls
++ meatAxe(aG,true,numberOfTries,7).
++ Notes: 7 covers the case of three-dimensional

```

```

++ kernels over the field with 2 elements.
scanOneDimSubspaces: (L V R, I) -> V R
++ scanOneDimSubspaces(basis,n) gives a canonical representative
++ of the n-th one-dimensional subspace of the vector space
++ generated by the elements of basis, all from R**n.
++ The coefficients of the representative are of shape
++ (0,...,0,1,...,*), * in R. If the size of R
++ is q, then there are (q**n-1)/(q-1) of them.
++ We first reduce n modulo this number, then find the
++ largest i such that +/[q**i for i in 0..i-1] <= n.
++ Subtracting this sum of powers from n results in an
++ i-digit number to basis q. This fills the positions of the
++ stars.

++ References:
++ Description:
++ This package provides coercions for the special types \spadtype{Exit}
++ and \spadtype{Void}.

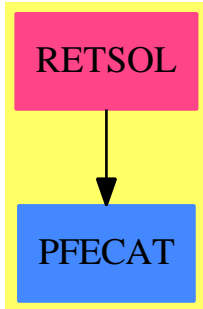

ResolveLatticeCompletion(S: Type): with
  coerce: S -> Void
    ++ coerce(s) throws all information about s away.
    ++ This coercion allows values of any type to appear
    ++ in contexts where they will not be used.
    ++ For example, it allows the resolution of different types in
    ++ the \spad{then} and \spad{else} branches when an \spad{if}
    ++ is in a context where the resulting value is not used.
  coerce: Exit -> S
    ++ coerce(e) is never really evaluated. This coercion is
    ++ used for formal type correctness when a function will not
    ++ return directly to its caller.
  
```

```
== add
  coerce(s: S): Void == void()
  coerce(e: Exit): S ==
    error "Bug: Should not be able to obtain value of type Exit"
```

RFP

PACRATC  
Exports:

distinguishedCommonRootsOf distinguishedRootsOf foundZeroes setFoundZeroes

```

(package RFP RootsFindingPackage)≡
)abbrev package RFP RootsFindingPackage
++ Authors: G. Hache
++ Date Created: 6 Oct 1994
++ Date Last Updated: May 2010 by Tim Daly
++ Description:
++ This package finds all the roots of a polynomial. If the constant field is
++ not large enough then it returns the list of found zeros and the degree
++ of the extension need to find the other roots missing. If the return
++ degree is 1 then all the roots have been found. If 0 is return
++ for the extension degree then there are an infinite number of zeros,
++ that is you ask for the zeroes of 0. In the case of infinite field
++ a list of all found zeros is kept and for each other call of a function
++ that finds zeroes, a check is made on that list; this is to keep
++ a kind of "canonical" representation of the elements.
RootsFindingPackage(K):P==T where
  K:Field

## 20.8 package SCACHE SortedCache

### 20.8.1 SortedCache (SCACHE)

#### Exports:

cache clearCache enterInCache

```

(package SCACHE SortedCache)≡
)abbrev package SCACHE SortedCache
++ Author: Manuel Bronstein
++ Date Created: 31 Oct 1988
++ Date Last Updated: 14 May 1991
++ Description:
++ A sorted cache of a cachable set S is a dynamic structure that
++ keeps the elements of S sorted and assigns an integer to each
++ element of S once it is in the cache. This way, equality and ordering
++ on S are tested directly on the integers associated with the elements
++ of S, once they have been entered in the cache.

```

SortedCache(S:CachableSet): Exports == Implementation where

N ==> NonNegativeInteger  
DIFF ==> 1024

Exports ==> with

```

clearCache : () -> Void
++ clearCache() empties the cache.
cache      : () -> List S
++ cache() returns the current cache as a list.
enterInCache: (S, S -> Boolean) -> S
++ enterInCache(x, f) enters x in the cache, calling \spad{f(y)} to
++ determine whether x is equal to y. It returns x with an integer
++ associated with it.
enterInCache: (S, (S, S) -> Integer) -> S
++ enterInCache(x, f) enters x in the cache, calling \spad{f(x, y)} to
++ determine whether \spad{x < y (f(x,y) < 0), x = y (f(x,y) = 0)}, or

```

```

++ \spad{x > y (f(x,y) > 0)}.
++ It returns x with an integer associated with it.

```

```

(package SRDCMPK SquareFreeRegularSetDecompositionPackage)≡
)abbrev package SRDCMPK SquareFreeRegularSetDecompositionPackage
++ Author: Marc Moreno Maza
++ Date Created: 09/23/1998
++ Date Last Updated: 12/16/1998
++ Basic Functions:
++ Related Constructors:
++ Also See:
++ AMS Classifications:
++ Keywords:
++ References :
++ [1] M. MORENO MAZA "A new algorithm for computing triangular
++      decomposition of algebraic varieties" NAG Tech. Rep. 4/98.
++ Description:
++ A package providing a new algorithm for solving polynomial systems
++ by means of regular chains. Two ways of solving are provided:
++ in the sense of Zariski closure (like in Kalkbrener's algorithm)
++ or in the sense of the regular zeros (like in Wu, Wang or Lazard-
++ Moreno methods). This algorithm is valid for nay type
++ of regular set. It does not care about the way a polynomial is
++ added in an regular set, or how two quasi-components are compared
++ (by an inclusion-test), or how the invertibility test is made in
++ the tower of simple extensions associated with a regular set.
  
```

### 20.13. PACKAGE SRDCMPK SQUAREFREEREGULARSETDECOMPOSITIONPACKAGE3475

```

++ These operations are realized respectively by the domain \spad{TS}
++ and the packages \spad{QCMPPK(R,E,V,P,TS)} and \spad{RSETGCD(R,E,V,P,TS)}.
++ The same way it does not care about the way univariate polynomial
++ gcds (with coefficients in the tower of simple extensions associated
++ with a regular set) are computed. The only requirement is that these
++ gcds need to have invertible initials (normalized or not).
++ WARNING. There is no need for a user to call diectly any operation
++ of this package since they can be accessed by the domain \axiomType{TS}.
++ Thus, the operations of this package are not documented.

```

```

```

<package MATSTOR StorageEfficientMatrixOperations>≡
)abbrev package MATSTOR StorageEfficientMatrixOperations
++ Author: Clifton J. Williamson
++ Date Created: 18 July 1990
++ Date Last Updated: 18 July 1990
++ Basic Operations:
++ Related Domains: Matrix(R)
++ Also See:
++ AMS Classifications:
++ Keywords: matrix, linear algebra
++ Examples:
++ References:
++ Description:
++ This package provides standard arithmetic operations on matrices.
++ The functions in this package store the results of computations
++ in existing matrices, rather than creating new matrices. This
++ package works only for matrices of type Matrix and uses the
++ internal representation of this type.
  
```

```

StorageEfficientMatrixOperations(R): Exports == Implementation where
R      : Ring

Exports ==> with
copy_! : (M,M) -> M
++ \spad{copy!(c,a)} copies the matrix \spad{a} into the matrix c.
++ Error: if \spad{a} and c do not have the same
++ dimensions.
plus_! : (M,M,M) -> M
++ \spad{plus!(c,a,b)} computes the matrix sum \spad{a + b} and stores the
++ result in the matrix c.
++ Error: if \spad{a}, b, and c do not have the same dimensions.
minus_! : (M,M) -> M
++ \spad{minus!(c,a)} computes \spad{-a} and stores the result in the
++ matrix c.
++ Error: if a and c do not have the same dimensions.
minus_! : (M,M,M) -> M
++ \spad{!minus!(c,a,b)} computes the matrix difference \spad{a - b}
++ and stores the result in the matrix c.
++ Error: if \spad{a}, b, and c do not have the same dimensions.
leftScalarTimes_! : (M,R,M) -> M
++ \spad{leftScalarTimes!(c,r,a)} computes the scalar product
++ \spad{r * a} and stores the result in the matrix c.
++ Error: if \spad{a} and c do not have the same dimensions.
rightScalarTimes_! : (M,M,R) -> M
++ \spad{rightScalarTimes!(c,a,r)} computes the scalar product
++ \spad{a * r} and stores the result in the matrix c.
++ Error: if \spad{a} and c do not have the same dimensions.
times_! : (M,M,M) -> M
++ \spad{times!(c,a,b)} computes the matrix product \spad{a * b}
++ and stores the result in the matrix c.
++ Error: if \spad{a}, b, and c do not have
++ compatible dimensions.
power_! : (M,M,M,M,NNI) -> M
++ \spad{power!(a,b,c,m,n)} computes  $m ** n$  and stores the result in
++ \spad{a}. The matrices b and c are used to store intermediate results.
++ Error: if \spad{a}, b, c, and m are not square
++ and of the same dimensions.
"*)" : (M,NNI) -> M
++ \spad{x ** n} computes the n-th power
++ of a square matrix. The power n is assumed greater than 1.

## 20.20 package STTAYLOR StreamTaylorSeriesOperations

Problems raising a UTS to a negative integer power.

The code in `powern(rn,x)` which raises an unnecessary error where no distinction between rational and integer powers are made.

The fix is easy. Since the problem does not exist in SUPS we can just take the definition there.

  "*"      : (ST A,A) -> ST A
            ++ a * r returns the power series scalar multiplication of \spad{a} by r:
            ++ \spad{[a0,a1,...] * r = [a0 * r,a1 * r,...]}
  "exquo"   : (ST A,ST A) -> Union(ST A,"failed")
            ++ exquo(a,b) returns the power series quotient of \spad{a} by b,
            ++ if the quotient exists, and "failed" otherwise
  "/"      : (ST A,ST A) -> ST A
            ++ a / b returns the power series quotient of \spad{a} by b.
            ++ An error message is returned if \spad{b} is not invertible.
            ++ This function is used in fixed point computations.
  recip     : ST A -> UN
            ++ recip(a) returns the power series reciprocal of \spad{a}, or

```

```

    ++ "failed" if not possible.
monom      : (A,I) -> ST A
    ++ monom(deg,coef) is a monomial of degree deg with coefficient
    ++ coef.
integers   : I -> ST I
    ++ integers(n) returns \spad{[n,n+1,n+2,...]}.
oddintegers : I -> ST I
    ++ oddintegers(n) returns \spad{[n,n+2,n+4,...]}.
int        : A -> ST A
    ++ int(r) returns [r,r+1,r+2,...], where r is a ring element.
mapmult    : (ST A,ST A) -> ST A
    ++ mapmult([a0,a1,...],[b0,b1,...])
    ++ returns \spad{[a0*b0,a1*b1,...]}.
deriv      : ST A -> ST A
    ++ deriv(a) returns the derivative of the power series with
    ++ respect to the power series variable. Thus
    ++ \spad{deriv([a0,a1,a2,...])} returns \spad{[a1,2 a2,3 a3,...]}.
gderiv     : (I -> A,ST A) -> ST A
    ++ gderiv(f,[a0,a1,a2,...]) returns
    ++ \spad{[f(0)*a0,f(1)*a1,f(2)*a2,...]}.
coerce     : A -> ST A
    ++ coerce(r) converts a ring element r to a stream with one element.
eval       : (ST A,A) -> ST A
    ++ eval(a,r) returns a stream of partial sums of the power series
    ++ \spad{a} evaluated at the power series variable equal to r.
compose    : (ST A,ST A) -> ST A
    ++ compose(a,b) composes the power series \spad{a} with
    ++ the power series b.
lagrange   : ST A -> ST A
    ++ lagrange(g) produces the power series for f where f is
    ++ implicitly defined as \spad{f(z) = z*g(f(z))}.
revert     : ST A -> ST A
    ++ revert(a) computes the inverse of a power series \spad{a}
    ++ with respect to composition.
    ++ the series should have constant coefficient 0 and first
    ++ order coefficient 1.
adddiag    : ST ST A -> ST A
    ++ adddiag(x) performs diagonal addition of a stream of streams. if x =
    ++ \spad{[[a<0,0>,a<0,1>,...],[a<1,0>,a<1,1>,...],[a<2,0>,a<2,1>,...],...]}
    ++ and \spad{adddiag(x) = [b<0,b<1>,...], then b<k> = sum(i+j=k,a<i,j>)}.
lambert    : ST A -> ST A
    ++ lambert(st) computes \spad{f(x) + f(x**2) + f(x**3) + ...}
    ++ if st is a stream representing \spad{f(x)}.
    ++ This function is used for computing infinite products.
    ++ If \spad{f(x)} is a power series with constant coefficient 1 then
    ++ \spad{prod(f(x**n),n = 1..infinity) = exp(lambert(log(f(x))))}.

```

```

oddlambert : ST A -> ST A
++ oddlambert(st) computes \spad{f(x) + f(x**3) + f(x**5) + ...}
++ if st is a stream representing \spad{f(x)}.
++ This function is used for computing infinite products.
++ If f(x) is a power series with constant coefficient 1 then
++ \spad{prod(f(x**(2*n-1)),n=1..infinity) = exp(oddlambert(log(f(x))))}.
evenlambert : ST A -> ST A
++ evenlambert(st) computes \spad{f(x**2) + f(x**4) + f(x**6) + ...}
++ if st is a stream representing \spad{f(x)}.
++ This function is used for computing infinite products.
++ If \spad{f(x)} is a power series with constant coefficient 1, then
++ \spad{prod(f(x**(2*n)),n=1..infinity) = exp(evenlambert(log(f(x))))}.
generallambert : (ST A,I,I) -> ST A
++ generallambert(f(x),a,d) returns
++ \spad{f(x**a) + f(x**(a + d)) + f(x**(a + 2 d)) + ...}.
++ \spad{f(x)} should have zero constant
++ coefficient and \spad{a} and d should be positive.
multisect : (I,I,ST A) -> ST A
++ multisect(a,b,st)
++ selects the coefficients of \spad{x**((a+b)*n+a)},
++ and changes them to \spad{x**n}.
invmultisect : (I,I,ST A) -> ST A
++ invmultisect(a,b,st) substitutes \spad{x**((a+b)*n)} for \spad{x**n}
++ and multiplies by \spad{x**b}.
if A has Algebra RN then
integrate : (A,ST A) -> ST A
++ integrate(r,a) returns the integral of the power series \spad{a}
++ with respect to the power series variable integration where
++ r denotes the constant of integration. Thus
++ \spad{integrate(a,[a0,a1,a2,...]) = [a,a0,a1/2,a2/3,...]}.
lazyIntegrate : (A,() -> ST A) -> ST A
++ lazyIntegrate(r,f) is a local function
++ used for fixed point computations.
nlde : ST ST A -> ST A
++ nlde(u) solves a
++ first order non-linear differential equation described by u of the
++ form \spad{[[b<0,0>,b<0,1>,...],[b<1,0>,b<1,1>,...]}.
++ the differential equation has the form
++ \spad{y'=sum(i=0 to infinity,j=0 to infinity,b<i,j>*(x**i)*(y**j))}.
powern : (RN,ST A) -> ST A
++ powern(r,f) raises power series f to the power r.
if A has Field then
mapdiv : (ST A,ST A) -> ST A
++ mapdiv([a0,a1,...],[b0,b1,...]) returns
++ \spad{[a0/b0,a1/b1,...]}.
lazyGintegrate : (I -> A,A,() -> ST A) -> ST A

```

```

    ++ lazyGintegrate(f,r,g) is used for fixed point computations.
    power      : (A,ST A) -> ST A
    ++ power(a,f) returns the power series f raised to the power \spad{a}.

## 20.28 package ODESYS SystemODESolver

### 20.28.1 SystemODESolver (ODESYS)

#### Exports:

solve solveInField triangulate

*<package ODESYS SystemODESolver>≡*

)abbrev package ODESYS SystemODESolver

++ Author: Manuel Bronstein

++ Date Created: 11 June 1991

++ Date Last Updated: 13 April 1994

++ Keywords: differential equation, ODE, system

++ Description:

++ SystemODESolver provides tools for triangulating

++ and solving some systems of linear ordinary differential equations.

SystemODESolver(F, LO): Exports == Implementation where

F : Field

LO: LinearOrdinaryDifferentialOperatorCategory F

N ==> NonNegativeInteger

Z ==> Integer

MF ==> Matrix F

M ==> Matrix LO

V ==> Vector F

UF ==> Union(F, "failed")

UV ==> Union(V, "failed")

REC ==> Record(mat: M, vec: V)

FSL ==> Record(particular: UF, basis: List F)

VSL ==> Record(particular: UV, basis: List V)

SOL ==> Record(particular: F, basis: List F)

USL ==> Union(SOL, "failed")

ER ==> Record(C: MF, g: V, eq: LO, rh: F)

```

Exports ==> with
triangulate: (MF, V) -> Record(A:MF, eqs: List ER)
  ++ triangulate(M,v) returns
  ++ \spad{A,[[C_1,g_1,L_1,h_1],...,[C_k,g_k,L_k,h_k]]}
  ++ such that under the change of variable \spad{y = A z}, the first
  ++ order linear system \spad{D y = M y + v} is uncoupled as
  ++ \spad{D z_i = C_i z_i + g_i} and each \spad{C_i} is a companion
  ++ matrix corresponding to the scalar equation \spad{L_i z_j = h_i}.
triangulate: (M, V) -> REC
  ++ triangulate(m, v) returns \spad{[m_0, v_0]} such that \spad{m_0}
  ++ is upper triangular and the system \spad{m_0 x = v_0} is equivalent
  ++ to \spad{m x = v}.
solve: (MF,V,(LO,F)->USL) -> Union(Record(particular:V, basis:MF),"failed")
  ++ solve(m, v, solve) returns \spad{[[v_1,...,v_m], v_p]} such that
  ++ the solutions in \spad{F} of the system \spad{D x = m x + v} are
  ++ \spad{v_p + c_1 v_1 + ... + c_m v_m} where the \spad{c_i's} are
  ++ constants, and the \spad{v_i's} form a basis for the solutions of
  ++ \spad{D x = m x}.
  ++ Argument \spad{solve} is a function for solving a single linear
  ++ ordinary differential equation in \spad{F}.
solveInField: (M, V, (LO, F) -> FSL) -> VSL
  ++ solveInField(m, v, solve) returns \spad{[[v_1,...,v_m], v_p]} such
  ++ that the solutions in \spad{F} of the system \spad{m x = v} are
  ++ \spad{v_p + c_1 v_1 + ... + c_m v_m} where the \spad{c_i's} are
  ++ constants, and the \spad{v_i's} form a basis for the solutions of
  ++ \spad{m x = 0}.
  ++ Argument \spad{solve} is a function for solving a single linear
  ++ ordinary differential equation in \spad{F}.

++ Also See: LinearSystemMatrixPackage, GroebnerSolve
++ AMS Classifications:
++ Keywords:
++ References:
++ Description:
++ Symbolic solver for systems of rational functions with coefficients
++ in an integral domain R.
++ The systems are solved in the field of rational functions over R.
++ Solutions are exact of the form variable = value when the value is
++ a member of the coefficient domain R. Otherwise the solutions
++ are implicitly expressed as roots of univariate polynomial equations over R.
++ Care is taken to guarantee that the denominators of the input
++ equations do not vanish on the solution sets.
++ The arguments to solve can either be given as equations or
++ as rational functions interpreted as equal
++ to zero. The user can specify an explicit list of symbols to
++ be solved for, treating all other symbols appearing as parameters
++ or omit the list of symbols in which case the system tries to
++ solve with respect to all symbols appearing in the input.

++    Bayreuther Mathematische Schriften, Heft 33, 1990, 1-23.
++ Description:
++ SymmetricGroupCombinatoricFunctions contains combinatoric
++ functions concerning symmetric groups and representation
++ theory: list young tableaux, improper partitions, subsets
++ bijection of Coleman.

```

```

SymmetricGroupCombinatoricFunctions(): public == private where

```

```

NNI ==> NonNegativeInteger
I   ==> Integer
L   ==> List
M   ==> Matrix
V   ==> Vector
B   ==> Boolean
ICF ==> IntegerCombinatoricFunctions Integer

```

```

public ==> with

```

```

--    IS THERE A WORKING DOMAIN Tableau ??
--    coerce : M I -> Tableau(I)
--    ++ coerce(ytab) coerces the Young-Tableau ytab to an element of
--    ++ the domain Tableau(I).

```

```

coleman : (L I, L I, L I) -> M I
++ coleman(alpha,beta,pi):
++ there is a bijection from the set of matrices having nonnegative
++ entries and row sums alpha, column sums beta
++ to the set of Salpha - Sbeta double cosets of the
++ symmetric group Sn. (Salpha is the Young subgroup
++ corresponding to the improper partition alpha).
++ For a representing element pi of such a double coset,
++ coleman(alpha,beta,pi) generates the Coleman-matrix
++ corresponding to alpha, beta, pi.
++ Note that The permutation pi of {1,2,...,n} has to be given
++ in list form.
++ Note that the inverse of this map is inverseColeman
++ (if pi is the lexicographical smallest permutation
++ in the coset). For details see James/Kerber.

```

```

inverseColeman : (L I, L I, M I) -> L I
++ inverseColeman(alpha,beta,C):
++ there is a bijection from the set of matrices having nonnegative
++ entries and row sums alpha, column sums beta
++ to the set of Salpha - Sbeta double cosets of the
++ symmetric group Sn. (Salpha is the Young subgroup

```

```

++ corresponding to the improper partition alpha).
++ For such a matrix C, inverseColeman(alpha,beta,C)
++ calculates the lexicographical smallest pi in the
++ corresponding double coset.
++ Note that the resulting permutation pi of {1,2,...,n}
++ is given in list form.
++ Notes: the inverse of this map is coleman.
++ For details, see James/Kerber.
listYoungTableaus : (L I) -> L M I
++ listYoungTableaus(lambda) where lambda is a proper partition
++ generates the list of all standard tableaus of shape lambda
++ by means of lattice permutations. The numbers of the lattice
++ permutation are interpreted as column labels. Hence the
++ contents of these lattice permutations are the conjugate of
++ lambda.
++ Notes: the functions nextLatticePermutation and
++ makeYoungTableau are used.
++ The entries are from 0,...,n-1.
makeYoungTableau : (L I, L I) -> M I
++ makeYoungTableau(lambda,gitter) computes for a given lattice
++ permutation gitter and for an improper partition lambda
++ the corresponding standard tableau of shape lambda.
++ Notes: see listYoungTableaus.
++ The entries are from 0,...,n-1.
nextColeman : (L I, L I, M I) -> M I
++ nextColeman(alpha,beta,C) generates the next Coleman matrix
++ of column sums alpha and row sums beta according
++ to the lexicographical order from bottom-to-top.
++ The first Coleman matrix is achieved by C=new(1,1,0).
++ Also, new(1,1,0) indicates that C is the last Coleman matrix.
nextLatticePermutation : (L I, L I, B) -> L I
++ nextLatticePermutation(lambda,lattP,constructNotFirst) generates
++ the lattice permutation according to the proper partition
++ lambda succeeding the lattice permutation lattP in
++ lexicographical order as long as constructNotFirst is true.
++ If constructNotFirst is false, the first lattice permutation
++ is returned.
++ The result nil indicates that lattP has no successor.
nextPartition : (V I, V I, I) -> V I
++ nextPartition(gamma,part,number) generates the partition of
++ number which follows part according to the right-to-left
++ lexicographical order. The partition has the property that
++ its components do not exceed the corresponding components of
++ gamma. The first partition is achieved by part=[].
++ Also, [] indicates that part is the last partition.
nextPartition : (L I, V I, I) -> V I

```

```

++ nextPartition(gamma,part,number) generates the partition of
++ number which follows part according to the right-to-left
++ lexicographical order. The partition has the property that
++ its components do not exceed the corresponding components of
++ gamma. the first partition is achieved by part=[].
++ Also, [] indicates that part is the last partition.
numberOfImproperPartitions: (I,I) -> I
++ numberOfImproperPartitions(n,m) computes the number of partitions
++ of the nonnegative integer n in m nonnegative parts with regarding
++ the order (improper partitions).
++ Example: numberOfImproperPartitions (3,3) is 10,
++ since [0,0,3], [0,1,2], [0,2,1], [0,3,0], [1,0,2], [1,1,1],
++ [1,2,0], [2,0,1], [2,1,0], [3,0,0] are the possibilities.
++ Note that this operation has a recursive implementation.
subSet : (I,I,I) -> L I
++ subSet(n,m,k) calculates the k-th m-subset of the set
++ 0,1,...,(n-1) in the lexicographic order considered as
++ a decreasing map from 0,...,(m-1) into 0,...,(n-1).
++ See S.G. Williamson: Theorem 1.60.
++ Error: if not (0 <= m <= n and 0 <= k < (n choose m)).
unrankImproperPartitions0 : (I,I,I) -> L I
++ unrankImproperPartitions0(n,m,k) computes the k-th improper
++ partition of nonnegative n in m nonnegative parts in reverse
++ lexicographical order.
++ Example: [0,0,3] < [0,1,2] < [0,2,1] < [0,3,0] <
++ [1,0,2] < [1,1,1] < [1,2,0] < [2,0,1] < [2,1,0] < [3,0,0].
++ Error: if k is negative or too big.
++ Note that counting of subtrees is done by
++ numberOfImproperPartitions
unrankImproperPartitions1: (I,I,I) -> L I
++ unrankImproperPartitions1(n,m,k) computes the k-th improper
++ partition of nonnegative n in at most m nonnegative parts
++ ordered as follows: first, in reverse
++ lexicographically according to their non-zero parts, then
++ according to their positions (i.e. lexicographical order
++ using subSet: [3,0,0] < [0,3,0] < [0,0,3] < [2,1,0] <
++ [2,0,1] < [0,2,1] < [1,2,0] < [1,0,2] < [0,1,2] < [1,1,1].
++ Note that counting of subtrees is done by
++ numberOfImproperPartitionsInternal.

## 21.4 package UTSSOL TaylorSolve

UTSSOL is a facility to compute the first few coefficients of a Taylor series given only implicitly by a function  $f$  that vanishes when applied to the Taylor series.

It uses the method of undetermined coefficients.

```
Could I either
\begin{itemize}
\item take a function  $\text{UTSCAT}\ F \rightarrow \text{UTSCAT}\ F$  and still be able to compute
  with undetermined coefficients, or
\item take a function  $F \rightarrow F$ , and do likewise?
\end{itemize}
```

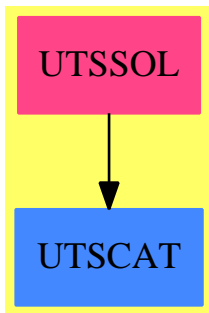

Let's see.

Try to compute the equation without resorting to power series. I.e., %  
 $c:\text{SUP}\ \text{SUP}\ F$ , and  $f:\text{SUP}\ \text{SUP}\ F \rightarrow \text{SUP}\ \text{SUP}\ F$ . Won't this make the  
 computation of coefficients terribly slow?

I could also try to replace transcendental kernels with variables\dots

Unfortunately,  $\text{SUP}\ F$  does not have  $\text{TRANFUN}$  -- well, it can't, of  
 course. However, I'd like to be able to compute %  
 $\sin(1+\text{monomial}(1,1)\text{UFPS}\ \text{SUP}\ \text{EXPR}\ \text{INT})$ .

### 21.4.1 TaylorSolve (UTSSOL)

#### Exports:

seriesSolve

```
(package UTSSOL TaylorSolve)≡
)abbrev package UTSSOL TaylorSolve
++ Description:
++ This package has no description
```

```

TaylorSolve(F, UTSF, UTSSUPF): Exports == Implementation where
  F: Field
  SUP ==> SparseUnivariatePolynomialExpressions
  UTSF: UnivariateTaylorSeriesCategory F
  UTSSUPF: UnivariateTaylorSeriesCategory SUP F
  NNI ==> NonNegativeInteger

  Exports == with
    seriesSolve: (UTSSUPF -> UTSSUPF, List F) -> UTSF

  Implementation == add
    <implementation: UTSSOL TaylorSolve>

<implementation: UTSSOL TaylorSolve>≡
  seriesSolve(f, l) ==
    c1 :=
      map((x:F):SUP F +-> x::(SUP F), l)
      $ListFunctions2(F, SUP F)::(Stream SUP F)
    coeffs: Stream SUP F := concat(c1, generate(monomial(1$F,1$NNI)))
  --
    coeffs: Stream SUP F := concat(c1, monomial(1$F,1$NNI))

coeffs is the stream of the already computed coefficients of the solution, plus one which is so
far undetermined. We store in st.2 the complete stream and in st.1 the stream starting with
the first coefficient that has possibly not yet been computed.

The mathematics is not quite worked out. If {\tt}coeffs} is initialized as
stream with all coefficients set to the \emph{same} transcendental value,
and not enough initial values are given, then the missing ones are
implicitly assumed to be all identical. It may well happen that a solution
is produced, although it is not uniquely determined\dots

<implementation: UTSSOL TaylorSolve>+≡
  st: List Stream SUP F := [coeffs, coeffs]

```

Consider an arbitrary equation  $f(x, y(x)) = 0$ . When setting  $x = 0$ , we obtain  $f(0, y(0)) = 0$ . It is not necessarily the case that this determines  $y(0)$  uniquely, so we need one initial value that satisfies this equation.

`{\tt{seriesSolve}}` should check that the given initial values satisfy  $f(0, y(0), y'(0), \dots) = 0$ .

Now consider the derivatives of  $f$ , where we write  $y$  instead of  $y(x)$  for better readability:

$$\frac{d}{dx}f(x, y) = f_1(x, y) + f_2(x, y)y'$$

and

```
\frac{d^2}{dx^2}f(x, y)&=f_{1,1}(x, y)\backslash\backslash
&+f_{1,2}(x, y)y^{\prime}\backslash\backslash
&+f_{2,1}(x, y)y^{\prime}\backslash\backslash
&+f_{2,2}(x, y)(y^{\prime})^2\backslash\backslash
&+f_2(x, y)y^{\prime\prime}.
```

In general,  $\frac{d^2}{dx^2}f(x, y)$  depends only linearly on  $y''$ .

This points to another possibility: Since we know that we only need to solve linear equations, we could compute two values and then use interpolation. This might be a bit slower, but more importantly: can we still check that we have enough initial values? Furthermore, we then really need that  $f$  is analytic, i.e., operators are not necessarily allowed anymore. However, it seems that composition is allowed.

```
<implementation: UTSSOL TaylorSolve>+≡
  next: () -> F :=
    nr := st.1
    res: F

    if ground?(coeff: SUP F := nr.1)$(SUP F)
```

If the next element was already calculated, we can simply return it:

```
<implementation: UTSSOL TaylorSolve>+≡
  then
    res := ground coeff
    st.1 := rest nr
  else
```

Otherwise, we have to find the first non-satisfied relation and solve it. It should be linear, or a single non-constant monomial. That is, the solution should be unique.

*(implementation: UTSSOL TaylorSolve)*+≡

```

    ns := st.2
    eqs: Stream SUP F := coefficients f series ns
    while zero? first eqs repeat eqs := rest eqs
    eq: SUP F := first eqs
    if degree eq > 1 then
        if monomial? eq then res := 0
    else
        output(hconcat("The equation is: ", eq::OutputForm))
            $OutputPackage
        error "seriesSolve: equation for coefficient not line
    else res := (-coefficient(eq, 0$NNI)$(SUP F)
        /coefficient(eq, 1$NNI)$(SUP F))

    nr.1 := res::SUP F
--      concat!(st.2, monomial(1$F,1$NNI))
    st.1 := rest nr

Implementation ==> add

I have had to work my way around the following bug in the compiler: When a local variable is given a mapping as a value, e.g.

```
foo : SF -> SF := makeFloatFunction(f,t),
```

the compiler cannot distinguish that local variable from a local function defined elsewhere in the package. Thus, when 'foo' is passed to a function, e.g.

```
bird := fcn(foo),
```

foo will often be compiled as |DRAW;foo| rather than |foo|. This, of course, causes a run-time error.

To avoid this problem, local variables are not given mappings as values, but rather (singleton) lists of mappings. The first element of the list can always be extracted and everything goes through as before. There is no major loss in efficiency, as the computation of points will always dominate the computation time.

The function `myTrap1` is a local function for used in creating maps `SF -> Point SF` (two dimensional). The range of this function is `SingleFloat`. As originally coded it would return `$NaNvalue$Lisp` which is outside the range. Since this function is only used internally by the `draw` package we handle the “failed” case by returning zero. We handle the out-of-range case by returning the maximum or minimum `SingleFloat` value.

Exports ==> with
  expand      : F -> F
    ++ expand(f) performs the following expansions on f:\begin{items}
    ++ \item 1. logs of products are expanded into sums of logs,
    ++ \item 2. trigonometric and hyperbolic trigonometric functions
    ++ of sums are expanded into sums of products of trigonometric
    ++ and hyperbolic trigonometric functions.
    ++ \item 3. formal powers of the form \spad{(a/b)**c} are expanded into
    ++ \spad{a**c * b**(-c)}.
    ++ \end{items}
  simplify    : F -> F
    ++ simplify(f) performs the following simplifications on f:\begin{items}
    ++ \item 1. rewrites trigs and hyperbolic trigs in terms
    ++ of \spad{sin} ,\spad{cos}, \spad{sinh}, \spad{cosh}.
    ++ \item 2. rewrites \spad{sin**2} and \spad{sinh**2} in terms
    ++ of \spad{cos} and \spad{cosh},
    ++ \item 3. rewrites \spad{exp(a)*exp(b)} as \spad{exp(a+b)}.
    ++ \item 4. rewrites \spad{(a**(1/n))**m * (a**(1/s))**t} as a single
    ++ power of a single radical of \spad{a}.
    ++ \end{items}
  htrigs      : F -> F
    ++ htrigs(f) converts all the exponentials in f into
    ++ hyperbolic sines and cosines.
  simplifyExp: F -> F
    ++ simplifyExp(f) converts every product \spad{exp(a)*exp(b)}
    ++ appearing in f into \spad{exp(a+b)}.
  simplifyLog : F -> F
    ++ simplifyLog(f) converts every \spad{log(a) - log(b)} appearing in f
    ++ into \spad{log(a/b)}, every \spad{log(a) + log(b)} into \spad{log(a*b)}
    ++ and every \spad{n*log(a)} into \spad{log(a^n)}.
  expandPower: F -> F
    ++ expandPower(f) converts every power \spad{(a/b)**c} appearing
    ++ in f into \spad{a**c * b**(-c)}.
  expandLog    : F -> F
    ++ expandLog(f) converts every \spad{log(a/b)} appearing in f into
    ++ \spad{log(a) - log(b)}, and every \spad{log(a*b)} into
    ++ \spad{log(a) + log(b)}..
  cos2sec     : F -> F
    ++ cos2sec(f) converts every \spad{cos(u)} appearing in f into
    ++ \spad{1/sec(u)}.

```

```

cosh2sech : F -> F
++ cosh2sech(f) converts every \spad{cosh(u)} appearing in f into
++ \spad{1/sech(u)}.
cot2trig : F -> F
++ cot2trig(f) converts every \spad{cot(u)} appearing in f into
++ \spad{cos(u)/sin(u)}.
coth2trigh : F -> F
++ coth2trigh(f) converts every \spad{coth(u)} appearing in f into
++ \spad{cosh(u)/sinh(u)}.
csc2sin : F -> F
++ csc2sin(f) converts every \spad{csc(u)} appearing in f into
++ \spad{1/sin(u)}.
csch2sinh : F -> F
++ csch2sinh(f) converts every \spad{csch(u)} appearing in f into
++ \spad{1/sinh(u)}.
sec2cos : F -> F
++ sec2cos(f) converts every \spad{sec(u)} appearing in f into
++ \spad{1/cos(u)}.
sech2cosh : F -> F
++ sech2cosh(f) converts every \spad{sech(u)} appearing in f into
++ \spad{1/cosh(u)}.
sin2csc : F -> F
++ sin2csc(f) converts every \spad{sin(u)} appearing in f into
++ \spad{1/csc(u)}.
sinh2csch : F -> F
++ sinh2csch(f) converts every \spad{sinh(u)} appearing in f into
++ \spad{1/csch(u)}.
tan2trig : F -> F
++ tan2trig(f) converts every \spad{tan(u)} appearing in f into
++ \spad{sin(u)/cos(u)}.
tanh2trigh : F -> F
++ tanh2trigh(f) converts every \spad{tanh(u)} appearing in f into
++ \spad{sinh(u)/cosh(u)}.
tan2cot : F -> F
++ tan2cot(f) converts every \spad{tan(u)} appearing in f into
++ \spad{1/cot(u)}.
tanh2coth : F -> F
++ tanh2coth(f) converts every \spad{tanh(u)} appearing in f into
++ \spad{1/coth(u)}.
cot2tan : F -> F
++ cot2tan(f) converts every \spad{cot(u)} appearing in f into
++ \spad{1/tan(u)}.
coth2tanh : F -> F
++ coth2tanh(f) converts every \spad{coth(u)} appearing in f into
++ \spad{1/tanh(u)}.
removeCosSq: F -> F

```

```

    ++ removeCosSq(f) converts every \spad{cos(u)**2} appearing in f into
    ++ \spad{1 - sin(x)**2}, and also reduces higher
    ++ powers of \spad{cos(u)} with that formula.
removeSinSq: F -> F
    ++ removeSinSq(f) converts every \spad{sin(u)**2} appearing in f into
    ++ \spad{1 - cos(x)**2}, and also reduces higher powers of
    ++ \spad{sin(u)} with that formula.
removeCoshSq: F -> F
    ++ removeCoshSq(f) converts every \spad{cosh(u)**2} appearing in f into
    ++ \spad{1 - sinh(x)**2}, and also reduces higher powers of
    ++ \spad{cosh(u)} with that formula.
removeSinhSq: F -> F
    ++ removeSinhSq(f) converts every \spad{sinh(u)**2} appearing in f into
    ++ \spad{1 - cosh(x)**2}, and also reduces higher powers
    ++ of \spad{sinh(u)} with that formula.
if R has PatternMatchable(R) and R has ConvertibleTo(Pattern(R))
and F has ConvertibleTo(Pattern(R)) and F has PatternMatchable R then
    expandTrigProducts : F -> F
        ++ expandTrigProducts(e) replaces \axiom{sin(x)*sin(y)} by
        ++ \spad{(cos(x-y)-cos(x+y))/2}, \axiom{cos(x)*cos(y)} by
        ++ \spad{(cos(x-y)+cos(x+y))/2}, and \axiom{sin(x)*cos(y)} by
        ++ \spad{(sin(x-y)+sin(x+y))/2}. Note that this operation uses
        ++ the pattern matcher and so is relatively expensive. To avoid
        ++ getting into an infinite loop the transformations are applied
        ++ at most ten times.

## 21.18.1 TransSolvePackage (SOLVETRA)

**Exports:**

solve

```

(package SOLVETRA TransSolvePackage)≡
)abbrev package SOLVETRA TransSolvePackage
++ Author: W. Wiwianka, Martin Rubey
++ Date Created: Summer 1991
++ Change History: 9/91
++ Basic Operations: solve
++ Related Constructors: RadicalSolvePackage, FloatingRealPackage
++ Keywords:
++ Description:
++ This package tries to find solutions of equations of type Expression(R).
++ This means expressions involving transcendental, exponential, logarithmic
++ and nthRoot functions.
++ After trying to transform different kernels to one kernel by applying
++ several rules, it calls zerosOf for the SparseUnivariatePolynomial in
++ the remaining kernel.
++ For example the expression \spad{sin(x)*cos(x)-2} will be transformed to
++ \spad{-2 tan(x/2)**4 -2 tan(x/2)**3 -4 tan(x/2)**2 +2 tan(x/2) -2}
++ by using the function normalize and then to
++ \spad{-2 tan(x)**2 + tan(x) -2}
++ with help of subsTan. This function tries to express the given function
++ in terms of \spad{tan(x/2)} to express in terms of \spad{tan(x)} .
++ Other examples are the expressions \spad{sqrt(x+1)+sqrt(x+7)+1} or
++ \spad{sqrt(sin(x))+1} .

### 21.19.1 TransSolvePackageService (SOLVESER)

#### Exports:

decomposeFunc unvectorise

*<package SOLVESER TransSolvePackageService>≡*

)abbrev package SOLVESER TransSolvePackageService

++ Author: W. Wiwianka

++ Date Created: Summer 1991

++ Change History: 9/91

++ Basic Operations: decomposeFunc, unvectorise

++ Related Constructors:

++ Keywords:

++ Description:

++ This package finds the function func3 where func1 and func2

++ are given and  $\text{func1} = \text{func3}(\text{func2})$ . If there is no solution then

++ function func1 will be returned.

++ An example would be \spad{func1:= 8\*X\*\*3+32\*X\*\*2-14\*X ::EXPR INT} and

++ \spad{func2:=2\*X ::EXPR INT} convert them via univariate

++ to FRAC SUP EXPR INT and then the solution is \spad{func3:=X\*\*3+X\*\*2-X}

++ of type FRAC SUP EXPR INT

#### Exports:

LowTriBddDenomInv UpTriBddDenomInv

```

(package TRIMAT TriangularMatrixOperations)=
)abbrev package TRIMAT TriangularMatrixOperations
++ Author: Victor Miller
++ Date Created:
++ Date Last Updated: 24 Jul 1990
++ Keywords:
++ Examples:
++ References:
++ Description:
++ This package provides functions that compute "fraction-free"
++ inverses of upper and lower triangular matrices over a integral
++ domain. By "fraction-free inverses" we mean the following:
++ given a matrix B with entries in R and an element d of R such that
++ d * inv(B) also has entries in R, we return d * inv(B). Thus,
++ it is not necessary to pass to the quotient field in any of our
++ computations.

```

++ Keywords:
++ Examples:
++ Description:
++ Tools for constructing tubes around 3-dimensional parametric curves.
  
```

TubePlotTools(): Exports == Implementation where

```

I   ==> Integer
SF  ==> DoubleFloat
L   ==> List
Pt  ==> Point SF
  
```

Exports ==> with

```

point: (SF,SF,SF,SF) -> Pt
++ point(x1,x2,x3,c) creates and returns a point from the three
++ specified coordinates \spad{x1}, \spad{x2}, \spad{x3}, and also
++ a fourth coordinate, c, which is generally used to specify the
++ color of the point.
"*" : (SF,Pt) -> Pt
++ s * p returns a point whose coordinates are the scalar multiple
++ of the point p by the scalar s, preserving the color, or fourth
++ coordinate, of p.
"+" : (Pt,Pt) -> Pt
  
```

```

++ p + q computes and returns a point whose coordinates are the sums
++ of the coordinates of the two points \spad{p} and \spad{q}, using
++ the color, or fourth coordinate, of the first point \spad{p}
++ as the color also of the point \spad{q}.
"--" : (Pt,Pt) -> Pt
++ p - q computes and returns a point whose coordinates are the
++ differences of the coordinates of two points \spad{p} and \spad{q},
++ using the color, or fourth coordinate, of the first point \spad{p}
++ as the color also of the point \spad{q}.
dot : (Pt,Pt) -> SF
++ dot(p,q) computes the dot product of the two points \spad{p}
++ and \spad{q} using only the first three coordinates, and returns
++ the resulting \spadtype{DoubleFloat}.
cross : (Pt,Pt) -> Pt
++ cross(p,q) computes the cross product of the two points \spad{p}
++ and \spad{q} using only the first three coordinates, and keeping
++ the color of the first point p. The result is returned as a point.
unitVector: Pt -> Pt
++ unitVector(p) creates the unit vector of the point p and returns
++ the result as a point. Note that \spad{unitVector(p)} = p/|p|.
cosSinInfo: I -> L L SF
++ cosSinInfo(n) returns the list of lists of values for n, in the form
++ \spad{[[cos(n-1) a,sin(n-1) a],...,[cos 2 a,sin 2 a],[cos a,sin a]]}
++ where \spad{a = 2 pi/n}. Note that n should be greater than 2.
loopPoints: (Pt,Pt,Pt,SF,L L SF) -> L Pt
++ loopPoints(p,n,b,r,lls) creates and returns a list of points
++ which form the loop with radius r, around the center point
++ indicated by the point p, with the principal normal vector of
++ the space curve at point p given by the point(vector) n, and the
++ binormal vector given by the point(vector) b, and a list of lists,
++ lls, which is the \spadfun{cosSinInfo} of the number of points
++ defining the loop.

## 21.24 package TWOFACT TwoFactorize

### 21.24.1 TwoFactorize (TWOFACT)

#### Exports:

generalSqFr generalTwoFactor twoFactor

*<package TWOFACT TwoFactorize>≡*

)abbrev package TWOFACT TwoFactorize

++ Authors : P.Gianni, J.H.Davenport

++ Date Created : May 1990

++ Date Last Updated: March 1992

++ Description:

++ A basic package for the factorization of bivariate polynomials

++ over a finite field.

++ The functions here represent the base step for the multivariate factorizer.

TwoFactorize(F) : C == T

where

F : FiniteFieldCategory

SUP ==> SparseUnivariatePolynomial

R ==> SUP F

P ==> SUP R

UPCF2 ==> UnivariatePolynomialCategoryFunctions2

C == with

generalTwoFactor : (P) -> Factored P

++ generalTwoFactor(p) returns the factorisation of polynomial p,

++ a sparse univariate polynomial (sup) over a

++ sup over F.

generalSqFr : (P) -> Factored P

++ generalSqFr(p) returns the square-free factorisation of polynomial p,

++ a sparse univariate polynomial (sup) over a

++ sup over F.

twoFactor : (P,Integer) -> Factored P

```

    ++ twoFactor(p,n) returns the factorisation of polynomial p,
    ++ a sparse univariate polynomial (sup) over a
    ++ sup over F.
    ++ Also, p is assumed primitive and square-free and n is the
    ++ degree of the inner variable of p (maximum of the degrees
    ++ of the coefficients of p).

## 24.2 package WFFINTBS WildFunctionFieldIntegralBasis

### 24.2.1 WildFunctionFieldIntegralBasis (WFFINTBS)

#### Exports:

integralBasis localIntegralBasis

```

<package WFFINTBS WildFunctionFieldIntegralBasis>≡
)abbrev package WFFINTBS WildFunctionFieldIntegralBasis
++ Authors: Victor Miller, Clifton Williamson
++ Date Created: 24 July 1991
++ Date Last Updated: 20 September 1994
++ Basic Operations: integralBasis, localIntegralBasis
++ Related Domains: IntegralBasisTools(R,UP,F),
++   TriangularMatrixOperations(R,Vector R,Vector R,Matrix R)
++ Also See: FunctionFieldIntegralBasis, NumberFieldIntegralBasis
++ AMS Classifications:
++ Keywords: function field, integral basis
++ Examples:
++ References:
++ Description:
++ In this package K is a finite field, R is a ring of univariate
++ polynomials over K, and F is a framed algebra over R. The package
++ provides a function to compute the integral closure of R in the quotient
++ field of F as well as a function to compute a "local integral basis"
++ at a specific prime.
  
```

```

=====
ZeroDimensionalSolvePackage examples
=====
```

The `ZeroDimensionalSolvePackage` package constructor provides operations for computing symbolically the complex or real roots of zero-dimensional algebraic systems.

The package provides no multiplicity information (i.e. some returned roots may be double or higher) but only distinct roots are returned.

Complex roots are given by means of univariate representations of irreducible regular chains. These representations are computed by the `univariateSolve` operation (by calling the `InternalRationalUnivariateRepresentationPackage` package constructor which does the job).

Real roots are given by means of tuples of coordinates lying in the `RealClosure` of the coefficient ring. They are computed by the `realSolve` and `positiveSolve` operations. The former computes all the solutions of the input system with real coordinates whereas the later concentrate on the solutions with (strictly) positive coordinates. In both cases, the computations are performed by the `RealClosure` constructor.

Both computations of complex roots and real roots rely on triangular decompositions. These decompositions can be computed in two different ways. First, by applying the `zeroSetSplit` operation from the `REGSET` domain constructor. In that case, no Groebner bases are computed. This strategy is used by default. Secondly, by applying the `zeroSetSplit` from `LEXTRIPK`. To use this later strategy with the operations `univariateSolve`, `realSolve` and `positiveSolve` one just needs to use an extra boolean argument.

Note that the way of understanding triangular decompositions is detailed in the example of the `RegularTriangularSet` constructor.

The `ZeroDimensionalSolvePackage` constructor takes three arguments. The first one `R` is the coefficient ring; it must belong to the categories `OrderedRing`, `EuclideanDomain`, `CharacteristicZero` and `RealConstant`. This means essentially that `R` is `Integer` or `Fraction(Integer)`. The second argument `ls` is the list of variables involved in the systems to solve. The third one `MUST BE concat(ls,s)` where `s` is an additional symbol used for the univariate representations. The abbreviation for `ZeroDimensionalSolvePackage` is `ZDSOLVE`.

We illustrate now how to use the constructor ZDSOLVE by two examples: the Arnborg and Lazard system and the L-3 system (Aubry and Moreno Maza). Note that the use of this package is also demonstrated in the example of the LexTriangularPackage constructor.

Define the coefficient ring.

```
R := Integer
Integer
Type: Domain
```

Define the lists of variables:

```
ls : List Symbol := [x,y,z,t]
[x,y,z,t]
Type: List Symbol
```

and:

```
ls2 : List Symbol := [x,y,z,t,new()$Symbol]
[x,y,z,t,%A]
Type: List Symbol
```

Call the package:

```
pack := ZDSOLVE(R,ls,ls2)
ZeroDimensionalSolvePackage(Integer,[x,y,z,t],[x,y,z,t,%A])
Type: Domain
```

Define a polynomial system (Arnborg-Lazard)

```
p1 := x**2*y*z + x*y**2*z + x*y*z**2 + x*y*z + x*y + x*z + y*z
      2      2      2
      x y z + (x y + (x + x + 1)y + x)z + x y
Type: Polynomial Integer
```

```
p2 := x**2*y**2*z + x*y**2*z**2 + x**2*y*z + x*y*z + y*z + x + z
      2 2      2 2      2
      x y z + (x y + (x + x + 1)y + 1)z + x
Type: Polynomial Integer
```

```
p3 := x**2*y**2*z**2 + x**2*y**2*z + x*y**2*z + x*y*z + x*z + z + 1
      2 2 2      2      2
      x y z + ((x + x)y + x y + x + 1)z + 1
Type: Polynomial Integer
```

```

lp := [p1, p2, p3]
      2      2      2
[x y z + (x y + (x + x + 1)y + x)z + x y,
      2 2      2 2      2
x y z + (x y + (x + x + 1)y + 1)z + x,
      2 2 2      2      2
x y z + ((x + x)y + x y + x + 1)z + 1]
      Type: List Polynomial Integer

```

Note that these polynomials do not involve the variable  $t$ ; we will use it in the second example.

First compute a decomposition into regular chains (i.e. regular triangular sets).

```

Type: List RegularChain(Integer,[x,y,z,t])

```

We can see easily from this decomposition (consisting of a single regular chain) that the input system has 20 complex roots.

Then we compute a univariate representation of this regular chain.

```

univariateSolve(lp)$pack

Type: List Record(complexRoots: SparseUnivariatePolynomial Integer,
coordinates: List Polynomial Integer)

```

We see that the zeros of our regular chain are split into three components. This is due to the use of univariate polynomial factorization.

Each of these components consist of two parts. The first one is an irreducible univariate polynomial  $p(?)$  which defines a simple algebraic extension of the field of fractions of  $R$ . The second one consists of multivariate polynomials  $\text{pol1}(x,\%A)$ ,  $\text{pol2}(y,\%A)$  and  $\text{pol3}(z,\%A)$ . Each of these polynomials involve two variables: one is an indeterminate  $x$ ,  $y$  or  $z$  of the input system  $\text{lp}$  and the other is  $\%A$  which represents any root of  $p(?)$ . Recall that this  $\%A$  is the last element of the third parameter of `ZDSOLVE`. Thus any complex root  $?$  of  $p(?)$  leads to a solution of the input system  $\text{lp}$  by replacing  $\%A$  by this  $?$  in  $\text{pol1}(x,\%A)$ ,  $\text{pol2}(y,\%A)$  and  $\text{pol3}(z,\%A)$ . Note that the polynomials  $\text{pol1}(x,\%A)$ ,  $\text{pol2}(y,\%A)$  and  $\text{pol3}(z,\%A)$  have degree one w.r.t.  $x$ ,  $y$  or  $z$  respectively. This is always the case for all univariate representations. Hence the operation `univariateSolve` replaces a system of multivariate polynomials by a list of univariate polynomials, what justifies its name. Another example of univariate representations illustrates the `LexTriangularPackage` package constructor.

We now compute the solutions with real coordinates:

```

        ]
    Type: List List RealClosure Fraction Integer

```

The number of real solutions for the input system is:

```

# lr
8
    Type: PositiveInteger

```

Each of these real solutions is given by a list of elements in `RealClosure(R)`. In these 8 lists, the first element is a value of `z`, the second of `y` and the last of `x`. This is logical since by setting the list of variables of the package to `[x,y,z,t]` we mean that the elimination ordering on the variables is  $t < z < y < x$ . Note that each system treated by the `ZDSOLVE` package constructor needs only to be zero-dimensional w.r.t. the variables involved in the system it-self and not necessarily w.r.t. all the variables used to define the package.

We can approximate these real numbers as follows. This computation takes between 30 sec. and 5 min, depending on your machine.

```

[ [approximate(r,1/1000000) for r in point] for point in lr]

]
]
```

Type: List List Fraction Integer

We can also concentrate on the solutions with real (strictly) positive coordinates:

```
lpr := positiveSolve(lp)$pack
[]
```

Type: List List RealClosure Fraction Integer

Thus we have checked that the input system has no solution with strictly positive coordinates.

Let us define another polynomial system (L-3).

```
f0 := x**3 + y + z + t- 1
      3
      z + y + x  + t - 1
      Type: Polynomial Integer
```

```
f1 := x + y**3 + z + t -1
      3
      z + y  + x + t - 1
      Type: Polynomial Integer
```

```
f2 := x + y + z**3 + t-1
      3
```

```

z3 + y + x + t - 1
Type: Polynomial Integer

```

```

f3 := x + y + z + t**3 - 1
      3
z3 + y + x + t - 1
Type: Polynomial Integer

```

```

lf := [f0, f1, f2, f3]
      3      3      3      3
[z3 + y + x + t - 1, z3 + y + x + t - 1, z3 + y + x + t - 1, z3 + y + x + t - 1]
Type: List Polynomial Integer

```

First compute a decomposition into regular chains (i.e. regular triangular sets).

```

lts := triangSolve(lf)$pack
[
  2      3      3
{t2 + t + 1, z3 - z - t3 + t,

Note that this computation is made from the input system lf.

However it is possible to reuse a pre-computed regular chain as follows:

```
ts := lts.1
      2      3      3
{t  + t + 1, z  - z - t  + t,
      3      2      2      3      6      3      3      2
(3z + 3t  - 3)y  + (3z  + (6t  - 6)z + 3t  - 6t  + 3)y + (3t  - 3)z
+
      6      3      9      6      3
(3t  - 6t  + 3)z + t  - 3t  + 5t  - 3t
,
x + y + z}
Type: RegularChain(Integer, [x,y,z,t])

univariateSolve(ts)$pack

      3      3      3      3      3
Type: List List RealClosure Fraction Integer

```

The number of real solutions for the input system is:

```

#l2r2
27

```

Type: PositiveInteger

Another example of computation of real solutions illustrates the LexTriangularPackage package constructor.

We concentrate now on the solutions with real (strictly) positive coordinates:

```

lpr2 := positiveSolve(lf)$pack
      1      3      1      1      3      1      1      3      1
[[[%B40,- - %B40 + -, - - %B40 + -, - - %B40 + -]]
      3      3      3      3      3
Type: List List RealClosure Fraction Integer

```

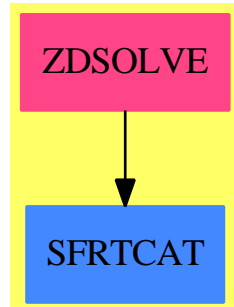

Finally, we approximate the coordinates of this point with 20 exact digits:

```
[approximate(r,1/10**21)::Float for r in lpr2.1]
[0.3221853546 2608559291, 0.3221853546 2608559291, 0.3221853546 2608559291,
 0.3221853546 2608559291]
Type: List Float
```

++ References:
++ Description:
++ A package for computing symbolically the complex and real roots of
++ zero-dimensional algebraic systems over the integer or rational
++ numbers. Complex roots are given by means of univariate representations
++ of irreducible regular chains. Real roots are given by means of tuples
++ of coordinates lying in the \spadtype{RealClosure} of the coefficient ring.
++ This constructor takes three arguments. The first one \spad{R} is the
++ coefficient ring. The second one \spad{ls} is the list of variables
++ involved in the systems to solve. The third one must be \spad{concat(ls,s)}
++ where \spad{s} is an additional symbol used for the univariate
++ representations.
++ WARNING. The third argument is not checked.
++ All operations are based on triangular decompositions.
++ The default is to compute these decompositions directly from the input
++ system by using the \spadtype{RegularChain} domain constructor.
++ The lexTriangular algorithm can also be used for computing these
++ decompositions (see \spadtype{LexTriangularPackage} package constructor).
++ For that purpose, the operations univariateSolve, realSolve and
++ positiveSolve admit an optional argument.
  
```

```

Exports == with
  triangSolve: (LP,B,B) -> List RegularChain(R,ls)
    ++ \spad{triangSolve(lp,info?,lextri?)} decomposes the variety
    ++ associated with \axiom{lp} into regular chains.
    ++ Thus a point belongs to this variety iff it is a regular
    ++ zero of a regular set in in the output.
    ++ Note that \axiom{lp} needs to generate a zero-dimensional ideal.
    ++ If \axiom{lp} is not zero-dimensional then the result is only
    ++ a decomposition of its zero-set in the sense of the closure
    ++ (w.r.t. Zarisky topology).
    ++ Moreover, if \spad{info?} is \spad{true} then some information is
    ++ displayed during the computations.

```

```

++ See zeroSetSplit from RegularTriangularSetCategory(lp,true,info?).
++ If \spad{lextri?} is \spad{true} then the lexTriangular algorithm
++ is called
++ from the \spadtype{LexTriangularPackage} constructor
++ (see zeroSetSplit from LexTriangularPackage(lp,false)).
++ Otherwise, the triangular decomposition is computed directly from
++ the input
++ system by using the zeroSetSplit from RegularChain
triangSolve: (LP,B) -> List RegularChain(R,ls)
